

Achievable rate regions and outer bounds for a multi-pair bi-directional relay network

Sang Joon Kim, Besma Smida and Natasha Devroye

Abstract

In a bi-directional relay channel, a pair of nodes wish to exchange independent messages over a shared wireless half-duplex channel with the help of relays. Recent work has mostly considered information theoretic limits of the bi-directional relay channel with two terminal nodes (or end users) and one relay. In this work we consider bi-directional relaying with one base station, multiple terminal nodes and one relay, all of which operate in half-duplex modes. We assume that each terminal node communicates with the base-station in a bi-directional fashion through the relay and do not place any restrictions on the channels between the users, relays and base-stations; that is, each node has a direct link with every other node. Our contributions are three-fold: 1) the introduction of four new temporal protocols which fully exploit the two-way nature of the data and outperform simple routing or multi-hop communication schemes by carefully combining network coding, random binning and user cooperation which exploit over-heard and own-message side information, 2) derivations of inner and outer bounds on the capacity region of the discrete-memoryless multi-pair two-way network, and 3) a numerical evaluation of the obtained achievable rate regions and outer bounds in Gaussian noise which illustrate the performance of the proposed protocols compared to simpler schemes, to each other, to the outer bounds, which highlight the relative gains achieved by network coding, random binning and compress-and-forward-type cooperation between terminal nodes.

I. INTRODUCTION

A. Goal and motivation

In this work, we will derive achievable rate regions and outer bounds for a multi-pair bi-directional relay network. The most basic bi-directional network consists of a pair of *terminal nodes* that wish to exchange independent messages. In wireless channels or mesh networks, this communication may take place with the help of *relay* nodes which do not wish to transmit any information of their own. The most basic bi-directional *relay* network thus consists of a pair of *terminal nodes* that wish to exchange messages through the relay of a single relay. While the capacity of this channel is still unknown in general, as will be outlined in the Related Work sub-section next, it has been of great recent interest due to its relevance in wireless networks of the future.

The single relay, single pair bi-directional relay channel has been extended in a number of ways: 1) the consideration of a single bi-directional link using *multiple relays*, 2) the consideration of *multiple bi-directional links* sharing a single, common relay or, most generally, 3) the consideration of multiple bi-directional links which communicate with the help of multiple relays.

The relay network considered in this paper falls into the second category and consists of a base station (node 0) which wishes to communicate simultaneously in a bi-directional fashion with multiple terminal nodes (node 1, $\dots$, node m) with the help of one relay node (node r). Due to limitations of current technology, all nodes are assumed to be half-duplex and thus cannot transmit and receive simultaneously. This network topology is motivated by recent pushes to extend the coverage of wireless networks. For example, in a cellular scenario, a relay station is able to enhance the connectivity between a base station and terminals at its cell boundary. The relays may be connected to the base station using a wireless link rather than a wired one, resulting in savings to the operators' backhaul costs. Another motivating example is satellite communication: satellites can be used to relay signals from one ground station to multiple vehicular terminals on or close to the earth's surface. In this work, we determine bounds on the capacity regions - which may serve as guides and benchmarks in the eventual design of - such multi-pair two-way communication networks aided by a single relay node.

B. Related work

Two-way communications were first considered by Shannon himself [39], in which he introduced inner and outer bounds on the capacity region of the two-way channel where two full-duplex nodes (which may transmit and receive simultaneously) wish to exchange messages. Since full-duplex operation is,

with current technology, of limited practical significance, in this work we assume that the nodes are *half-duplex*, i.e. at each point in time, a node can either transmit or receive symbols, but not both.

The two-way relay channel or bi-directional relay channel is the logical extension of the classical relay channel [7], [21], [41] for one-way point-to-point communication aided by a relay to allow for two-way communication. Alternatively, it may be seen as the natural extension of the two-way channel which allows communication to take place with the help of a single relay. This channel has been of great interest of late and has been considered from a number of different perspectives. A large body of work concerning the bi-directional relay channel - which we do not attempt to fully summarize - has emerged, which may be differentiated roughly based on combinations of assumptions that are made on the type of relaying (CF, DF, AF, de-noise, mixed, lattice codes) and on the duplex abilities of nodes (half-duplex or full-duplex). We highlight some of the work under different assumptions before proceeding to describe extensions to multiple terminal nodes and/or multiple relay nodes.

1. **Relaying type:** The simplest of relaying types is Amplify-and-forward (AF), in which relays are not required to do any processing on the received signal but re-scale and re-transmit it. AF schemes are often used as a benchmark against which to compare the performance of more complex relaying types [13], [16], [33]–[35], [37]. Decode and forward (DF) relaying assumes the relay is able to decode all messages before re-transmitting them. Examples of work which assume bi-directional DF relaying include [8], [16]–[18], [22], [23], [28], [30], [31], [36], [40], [47]. Using DF relaying allows the use of network coding at the message level for the broadcast phase and prevents the re-transmission and possible amplification of noise, at the cost of forcing the relays to decode the messages, possibly reducing the permissible transmission rates. Compress and forward (CF), as first introduced in the context of the classical relay channel [6], and considered in the bi-directional relaying context in [8], [17], [36] and the conceptually related de-noise and forward [35], [34], [33], requires the relay to re-transmit a quantized or compressed version of the received signal. This scheme has the advantage that the rate need not be lowered so as to allow the relay to fully decode it, but may still mitigate some of the noise amplification effects seen in AF relaying by judicious choice of the quantizer or compressor. In the authors' previous work, [16], [17] the *mixed* forwarding scheme is also proposed, in which the streams of information traveling in the two directions are treated differently, i.e. one direction may use DF while the other uses CF, exploiting the intuitive fact that DF is preferable when a relay is “close” to the source while CF is generally preferable, rate-wise when the relay is “close” to the destination [16], [21].

2. **Duplexing:** Both full-duplex as well as half-duplex nodes and their corresponding achievable rate regions have been considered for bi-directional relaying. In [8], [16], [17], [19], [22], [23], [28], [33]–

Fig. 1. Three most common half-duplex bi-directional relaying protocols: a naive 4 phase protocol, the 3 phase TDBC (Time Division Broadcast Channel) protocol and the 2 phase MABC (Multiple Access Broadcast Channel) protocol.

[35], [37], [42], [46], [48] half-duplex nodes are assumed. This forces communication to take place over a number of phases, using different temporal *protocols*. A temporal protocol specifies which nodes simultaneously transmit at which time. Three of the most commonly considered protocols are depicted in 1: the naive 4 phase protocol, the 3 phase time-division broadcast channel (TDBC) protocol, as well as the 2phase Multiple-access broadcast channel (MABC) protocol, where each “layer” of nodes describes a different temporal phase. It is interesting to note that in half-duplex protocols, the TDBC allows a destination to obtain *side-information*, or extra overheard knowledge, about the other user’s message during the phase in which the message is destined to the relay. This is not possible in 2 phase MABC protocols in which both nodes transmit simultaneously to the relay in one phase and are thus unable to overhear any of the other relay’s message. In [16], [19] it is shown that neither TDBC or MABC dominate each other for all channel gains and SNRs. In [14], [17] a comprehensive treatment of CF, DF, AF and mixed forwarding schemes under both the MABC and TDBC protocols highlights the significant interplay between relaying types and protocols. In [28], [30], [31], [40], [47] the authors have thoroughly analyzed the broadcast phase of the bi-directional relay channel. The full-duplex scenarios have been considered somewhat less: in [36] the authors derived achievable rate regions for the *restricted* two-way relay channel using DF, CF and AF schemes, in which the terminals may not cooperate in transmitting their messages. In [45] full-duplex nodes are considered in order to analyze the system from a finite bit perspective.

Extensions to multiple-relays and multiple terminal nodes. The bi-directional relay channel has been extended to include multiple relays [15], [18], [25], [29], [32], [43], [44] and multiple terminals

nodes (or multiple bi-directional data streams) [1], [4], [10], [11]. A variety of promising methods have been employed, but to date the capacity regions of these extensions are still unknown.

The study of a single bi-directional communication link aided by multiple relays has been approached from a number of angles [18], [25], [29], [32], [43], [44], which seek to address how to “best” employ the relays. How/which relays to select has been considered in unidirectional networks in for example [3], [24], [26] and was considered for the first time for bi-directional relay networks in [29]. Alternatively, multiple relays could amplify and forward the received signals in a multi-hop fashion, or may decode and cooperatively re-encode and re-transmit the received signals. In the authors’ previous work in [15], [18] three classes of multiple relays protocols for the half-duplex, non-adaptive DMC and AWGN channel models are considered and inner and outer bounds on the capacity region are derived.

Bi-directional relay channels with multiple bi-directional communication links have been much less considered than their single link counterpart:

- In [10] an interference network, with no direct links between terminal nodes, in which K half-duplex single-antenna source/destination pairs wish to exchange messages in a bi-directional fashion is investigated from a diversity-multiplexing gain perspective in the delay-limited high SNR regime.
- The authors of [4] consider a similar channel model and propose the use of a CDMA strategy to support multiple users so as to guarantee QoS to different users.
- In [1] multiple bi-directional pairs communicate over a shared relay in the absence of a direct link between end nodes. Under a linear deterministic channel interaction model, an interesting equation-forwarding strategy is shown to be capacity-achieving. This intuition is transferred to the two-pair full-duplex bi-directional Gaussian relay network in [38], where a carefully constructed superposition scheme of random and lattice codes was used to achieved rates within 2 bits of the outer cut-set bound.
- Finally, in [11], an arbitrary number of clusters (nodes within a cluster all wish to exchange messages) of arbitrary numbers of full-duplex nodes are assumed to communicate simultaneously through the use of a single relay in AWGN. Nodes are not able to hear each other, and it is shown that CF achieves within a constant number of bits from capacity regardless of SNR; interesting conclusions are also drawn with respect to lattice coding versus CF.

In all four examples of multi-pair bi-directional communication with a single relay, no direct link between the terminal nodes is assumed to exist. This simplifies the analysis as the tradeoff between relayed information and directly communicated information is avoided. No “overheard” side information from one terminal to the other is possible, and the only side information available in this channel is each node’s own message.

Fig. 2. Our physical channel model consists of multiple independent bi-directional desired communication flows (indicated by arrows) between multiple terminal nodes and a single base-station. Communications may be aided using one relay node. We note that communication need not pass through the relay as direct links between the base-station and terminals exist. $W_{i,j}$ denotes the message from node i to node j , while $\tilde{W}_{i,j}$ is the estimate at node j of the message $W_{i,j}$ that it wishes to decode.

C. Our contributions

We consider a bi-directional relay network with one base station, multiple terminal nodes and one relay, all of which operate in half-duplex mode. The physical layout is shown in Fig. 2. We assume that each terminal node communicates with the base-station in a bi-directional fashion through the relay and do not place any restrictions on the channels between the users, relays and base-stations; that is, each node has a direct link with every other node. The desired bi-directional links may be seen from the messages $W_{i,j}$ from node i destined to node j , and $\tilde{W}_{i,j}$ the estimate at node j of the message $W_{i,j}$ that it wishes to decode from node i . The base-station is denoted as as node with index 0. Two elements of the formulated problem are markedly different from prior work in this area:

- the assumption that one end of the bi-directional links is a single base-station rather than independent nodes as in [11], [38] and [10].
- we place no assumptions on the channels between nodes - i.e. our nodes can all hear each other. This allows for the possibility of causal cooperation between nodes as well as direct transmission between the base-station and the nodes, using the relay only when beneficial.

Our central contributions are three-fold:

1. We propose four temporal protocols which we call the FMABC (*Full Multiple Access Broadcast*), PMABC (*Partial Multiple Access Broadcast*) and FTDBC (*Full Time Division Broadcast*), PTDBC (*Partial Time Division Broadcast*) protocols: the first two are extensions of the MABC protocol of [16],

pictured in Fig.1 to multiple terminal-node pairs, while the last two are extensions of the TDBC protocol of [16], also pictured in Fig. 1 to multiple terminal nodes.

2. Our central goal is to determine inner and outer bounds on the capacity region of the multi-pair bi-directional relay network. To derive achievable rate regions we suggest a number of achievable strategies, the key elements of which are:

- *Forwarding*: We consider the decode-and-forward (DF) forwarding strategy at the relay node; and employ a Compress and Forward (CF) - type cooperation strategy at terminal nodes.
- *Multiple-access*: In contrast to the “naive” protocol of Fig. 1, we will consider schemes in which multiple nodes transmit simultaneously to a single node as in a multiple-access channel.
- *Marton’s broadcast region*: Due to the presence of a base-station with multiple messages (one to each of the terminal nodes) as well as a relay with multiple decoded messages (traveling in both directions), we use a *modified* version of a generalization of Marton’s broadcasting scheme [27] to > 2 messages/users, which takes into account own-message side-information at each node.
- *Random binning*: is used to exploit side-information from direct links as in the TDBC protocol in [16], with the added challenge that the direct links involve a general Marton broadcasting scheme.
- *Network coding*: We will use network coding on a *flow-by-flow* basis. The different bi-directional flows are then combined using a random binning / broadcasting strategy.
- *User cooperation*: “Over-heard” side information at terminal nodes is used to allow terminal nodes to cooperate - using a compress and forward strategy - in transmitting their messages.

D. Outline

This paper is structured as follows: in Section II. we introduce our notation and the different protocols we will be examining. In Section III we introduce the extended Marton’s bound for the general broadcast channel with more than two receivers. In Section IV we derive achievable rate regions for the proposed protocols with DF relaying and CF-based terminal node cooperation, while in Section V we derive outer bounds for those protocols. In Section VI, we apply the derived performance bounds to the Gaussian noise channel. In Section VII, we numerically compute these bounds in the Gaussian noise channel and compare the results for different powers and channel conditions, followed by the conclusion in Section VIII. The proofs of technical contributions are provided in the Appendices, while those for the bi-directional inner and outer bounds are provided in the body of the document.

II. PRELIMINARIES

A. Notations and Definitions

We consider a base station (node 0), a set of terminal nodes $\mathcal{B} := \{1, 2, \dots, m\}$ and a relay r which aids in the communication between the terminal nodes and the base station. We define $\mathcal{M} := \mathcal{B} \cup \{0\} = \{0, 1, 2, \dots, m\}$. We use $R_{i,j}$ to denote the rate of communication from node i to node j , i.e. the message between node i and node j , $W_{i,j}$, lies in the set $\mathcal{S}_{i,j} := \{0, \dots, \lfloor 2^{nR_{i,j}} \rfloor - 1\}$. Similarly, $R_{S,T}$ is the vector of rates from set S to set T where $S, T \subseteq \mathcal{M}$ at which the messages $W_{S,T} := \{W_{i,j} | i \in S, j \in T, S, T \subseteq \mathcal{M}\}$ may be reliably communicated. We assume that each end user communicates with the base station bi-directionally and that no information is directly exchanged between end users: i.e. every pair of terminal nodes 0 and $i \in \mathcal{B}$ wish to exchange independent messages while $R_{i,j} = 0$ (or is undefined) for all $i, j \in \mathcal{B}$. Thus, there are a total of $2m$ messages in our network: m from node 0 to each node $i \in \mathcal{B}$, and m from each node $i \in \mathcal{B}$ to node 0, as shown in Fig. 2¹.

Communication takes place over a number of channel uses, n and rates are achieved in the classical asymptotic sense as $n \rightarrow \infty$. At channel use k , we use X_i^k to denote the input distribution and Y_i^k to denote the distribution of the received signal of node i . During phase ℓ we use $X_i^{(\ell)}$ to denote the input distribution and $Y_i^{(\ell)}$ to denote the distribution of the received signal of node i . Because of the half-duplex constraint, not all nodes transmit/receive during all phases and we use the dummy symbol $\emptyset$ to denote that there is no input or no output at a particular node during a particular phase, i.e. we must have $X_i^{(\ell)} = \emptyset$ or $Y_i^{(\ell)} = \emptyset$ for all ℓ phases. For convenience, we drop the notation $\emptyset$ from entropy and the mutual information terms when a node is not transmitting or receiving. $\Delta_{i,n}$ is the phase duration of phase i with block size n and Δ_i is the phase duration of phase i when $n \rightarrow \infty$. It is also convenient to define $X_S^k := \{X_i^k | i \in S\}$, the set of input distributions by all nodes in the set S at time k and similarly $X_S^{(\ell)} := \{X_i^{(\ell)} | i \in S\}$, a set of input distributions during phase ℓ .

Each node i has channel input alphabet $\mathcal{X}_i^* = \mathcal{X}_i \cup \{\emptyset\}$ and channel output alphabet $\mathcal{Y}_i^* = \mathcal{Y}_i \cup \{\emptyset\}$, which are related through a discrete memoryless channel². Lower case letters x_i denote instances of the upper case X_i which lie in the calligraphic alphabets $\mathcal{X}_i^*$. Boldface $\mathbf{x}_i$ represents a vector indexed by time at node i . Finally, it is convenient to denote by $\mathbf{x}_S := \{\mathbf{x}_i | i \in S\}$, a set of vectors indexed by time. We also use the notation $\mathbf{x}_S(w_{S,T})$ to denote the dependence of $\mathbf{x}_S$ on the message set $w_{S,T}$.

¹We allow information exchanges between nodes in $\mathcal{B}$ in the cooperation protocols. However these messages are not induced from the system, but just used as temporary information for decoding original messages between node 0 and $\mathcal{B}$.

²Arguments and extensions to Gaussian noise channels will be addressed in Section VI.

For a block length n , encoders and decoders are functions $X_i^k(W_{\{i\},\mathcal{M}}, Y_i^1, \dots, Y_i^{k-1})$ producing an encoded message at node i , and $\tilde{W}_{i,j}(Y_j^1, \dots, Y_j^n, W_{\{j\},\mathcal{M}})$ producing a decoded message or error at node j when it wishes to decode the message $W_{i,j}$ from node i . We define error events $E_{S,T} := \{W_{i,j} \neq \tilde{W}_{i,j}(\cdot) | i \in S, j \in T\}$ for decoding the messages $W_{S,\{j\}}$ at nodes $j \in T$ at the end of the block of length n , and $E_{S,T}^{(\ell)}$ as the error event at nodes $j \in T$ in which nodes $j \in T$ independently attempt to decode $W_{S,T}$ at the end of phase ℓ using a joint typicality decoder. A set of rates $R_{i,j}$ is said to be achievable for a protocol with phase durations Δ_ℓ if there exist encoders/decoders of block length $n = 1, 2, \dots$ with both $P[E_{i,j}] \rightarrow 0$ and $\Delta_{\ell,n} \rightarrow \Delta_\ell$ as $n \rightarrow \infty$ for all ℓ . An achievable rate region (resp. capacity region) is the closure of a set of (resp. all) achievable rate tuples for Δ_ℓ .

Let $A(U)$ be the set of ϵ -strongly-typical $\mathbf{u}$ sequences. Similarly, $A^{(\ell)}(UV)$ represents the set of ϵ -strongly-typical $(\mathbf{u}^{(\ell)}, \mathbf{v}^{(\ell)})$ sequences of length $n \cdot \Delta_{\ell,n}$ according to the distributions U and V in phase ℓ . Also define the event $D^{(\ell)}(\mathbf{u}, \mathbf{v}) := \{(\mathbf{u}^{(\ell)}, \mathbf{v}^{(\ell)}) \in A^{(\ell)}(UV)\}$ and use $\bar{D}$ to denote the complement of the event D . Similarly, $\bar{E}$ is defined. We denote $\otimes$ as the cartesian product, i.e., $\otimes_{i=1}^3 \mathcal{X}_i = \mathcal{X}_1 \times \mathcal{X}_2 \times \mathcal{X}_3$. Finally, let $S(j) := \{i | i < j, i \in S\}$.

B. Protocols for multiple terminal-node pairs

The total transmission time is divided into two time *divisions*, each of which may consist of one or more *phases*. During the first time division - called the *multiple access* division, the terminal nodes transmit to the relay. During the second time division - called the *broadcast* division - the relay transmits to the terminal nodes. In the multiple access period, we consider four cases: 1) all terminal nodes transmit for the whole duration, 2) 0 uses the whole duration and the other terminal nodes $1, \dots, m$ transmit sequentially, 3) all nodes transmit sequentially and 4) 0 first transmits and the other terminal nodes multiple access. We denote the first protocol as *Full Multiple Access Broadcast* (FMABC) protocol, the second protocol as *Partial Multiple Access Broadcast* (PMABC) protocol, the third one as *Full Time Division Broadcast* (FTDBC) protocol, and the last one as *Partial Time Division Broadcast* (PTDBC) protocol. A more visual description of which nodes transmit when is provided in Fig. 3.

For comparison purposes in our simulations, we also introduce what we call the *simplest sequential protocol* where all terminal nodes sequentially transmit information to the relay, i.e., $0 \rightarrow r$, $1 \rightarrow r$, $\dots$, $m \rightarrow r$, then the relay sequentially transmits them to the proper destinations, i.e., $r \rightarrow 0$, $r \rightarrow 1$, $\dots$, $r \rightarrow m$.

The FMABC, PMABC, FTDBC, and PTDBC protocols describe the temporal phases or divisions of the transmission scheme but not what each node sends, or how its messages are encoded during those phases.

Fig. 3. Four proposed half-duplex protocols - the time phases of the different protocols are seen; the encoders and decoders in the different phases may vary.

We will exploit three types of coding schemes - network coding, random binning and user cooperation:

1) *Network Coding*: We will use network coding on a *flow-by-flow* (each flow consists of two bi-directional messages $W_{i,0}$ and $W_{0,i}$) basis to improve achievable rates. The relay r uses *decode and forward* (DF) scheme for broadcasting the received signals. The relay r estimates $\{w_{0,i}\}$ and $\{w_{i,0}\}$, at the end of the multiple access period, and constructs $w_{r_i} = w_{0,i} \oplus w_{i,0}$, $\forall i \in \mathcal{B}$. Next, the DF relay r constructs $w_r = (w_{r_1}, w_{r_2}, \dots, w_{r_m})$ and broadcasts $\mathbf{x}_r(w_r)$ during the broadcast period.

2) *Random binning*: Random binning is not only used in a Marton-like fashion but is further used to exploit side-information from direct links in the PMABC, FTDBC and PTDBC protocols. We apply random binning to combine, at an end user, the information received along from the direct link, and that received along the relaying link. Similar to the TDBC protocol of the single pair case in [16], we use random binning when the relay is transmitting to the destination nodes. Also, as in the Multi-Hop Multi-Relay protocol in [15], each terminal node listens to the other terminal nodes' signals whenever it is not transmitting itself, thereby building up side-information which may be exploited in decoding its own message after the relay broadcasting division/phase.

3) *Cooperation between terminal nodes*: As our channel model allows end users to over-hear the transmissions of the base-station and other end-nodes when they are not transmitting, over-heard side information is available at terminal nodes. This may be used to allow terminal nodes to cooperate in

transmitting their messages. Cooperation is enabled through a compress and forward strategy in which each terminal node in $\mathcal{B}$ compresses the signals received during the relay broadcast period using an auxiliary message set, which it then transmits during the next multiple access period. If other nodes can decode this auxiliary message, they are able to obtain the compressed received signals which in turn may be used to decode messages from the relay.

To concretely illustrate how our cooperation strategy operates, we describe cooperation for the PMABC protocol; the FTDBC protocol can be similarly constructed, and cooperation is impossible under the FMABC and PTDBC protocols (as there are no overhead messages). We apply the *sliding window* and *Compress and Forward* schemes when node $i \in \mathcal{B}$ is transmitting: first, we divide the total time duration into $K + 1$ slots and each slot consists of $m + 1$ phases. Every message $w_{i,j}$ is also divided into K blocks as $\{w_{i,j|(1)}, \dots, w_{i,j|(K)}\}$, and node i transmits $\{w_{i,j|(k)}\}$ during slot k and phase i (for PMABC). After relay r broadcasts $\mathbf{x}_r$ during slot k and phase $m + 1$, node i compress $\mathbf{y}_i$ to $\hat{\mathbf{y}}_i$ with auxiliary message set $\{w_{\{i\},\mathcal{B}}\}$. Then node i broadcasts $\mathbf{x}_i(w_{i,0|(k+1)}, w_{\{i\},\mathcal{B}|(k)})$ during slot $k + 1$ and phase i except for the first and last slots. During the first and last slot, i sends $\mathbf{x}_i(w_{i,0|(1)}, 1)$ and $\mathbf{x}_i(1, w_{\{i\},\mathcal{B}|(K)})$, respectively.

In general, joint typicality is non-transitive. However, by using strong joint-typicality, and the fact that for the distributions of interest $x \rightarrow y \rightarrow \hat{y}$, we will be able to argue joint typicality between $\mathbf{x}$ and $\hat{\mathbf{y}}$ by the *Markov lemma* (Lemma 4.1 in [2]). If node $j \in \mathcal{B}, j \neq i$ can decode $\tilde{w}_{\{i\},\mathcal{B}|(k)}$ at the end of slot $k + 1$ and phase i , node j can use the sequence $\hat{\mathbf{y}}_i^{(m+1)}(w_{\{i\},\mathcal{B}|(k)})$ for decoding $\tilde{w}_{0,j|(k)}$. Let $\mathcal{J}_j$ be the set of nodes whose message can be decoded by node j , i.e., $\mathcal{J}_j = \{i | \tilde{w}_{\{i\},\mathcal{B}|(k)} = w_{\{i\},\mathcal{B}|(k)}, \forall k \in [1, K + 1]\}$. Then node j uses the jointly typical sequences $(\mathbf{x}_r^{(m+1)}(w_r), \mathbf{y}_j^{(m+1)}, \hat{\mathbf{y}}_{\mathcal{J}_j}^{(m+1)}(w_{\mathcal{J}_j,\mathcal{B}|(k)}))$ to decode $\tilde{w}_{0,j|(k)}$. Fig. 4 illustrates an example of the PMABC protocol with $m = 2$ terminal nodes (and hence four messages).

In the remainder of this paper, we will be considering a number of different protocols combined with different encoding/decoding schemes. One of our goals is to determine whether all encoding schemes are useful and if so, under what channel conditions certain protocols/encoding schemes out-perform others. In Table I, we summarize the considered protocols and corresponding coding schemes. The indices/notation should be read as “N” means Network coding, “R” means Random binning, and “C” means Cooperation between end nodes. We will derive achievable rate regions for all protocols in the left hand column of Table I and derive an outer bound for FMABC, PMABC, FTDBC and PTDBC separately. All outer bounds are variations of cut-set outer bounds along the lines of [14]–[16].

Fig. 4. An example of the PMABC protocol with $m = 2$ and cooperation.

III. EXTENSION OF MARTON'S INNER BOUND

Due to the presence of > 2 independent messages at the relay who will wish to broadcast messages to the terminal and base-station nodes, for completeness, we first present a simple extension of Marton's achievable rate region for the 2 user discrete memoryless broadcast channel [27] to m independent receivers in the absence of common information. This Theorem will be used in the derivation of the achievable rate regions - where it will be carefully combined with the unique side-information available in a bi-directional relay channel, i.e. each node has knowledge of its own message.

Theorem 1: [Extended Marton] An achievable rate region for sending independent information over

the broadcast channel $X \rightarrow (Y_1, Y_2, \dots, Y_m)$ is the closure of all points $(R_1, \dots, R_m)$ satisfying

$$\sum_{i \in S} R_i < \sum_{i \in S} I(U_i; Y_i) - I(U_i; U_{S(i)}) \quad \forall S \subseteq \mathcal{B} \quad (1)$$

over all joint distributions $p(u_1, \dots, u_m, x)p(y_1, \dots, y_m|x)$, over the alphabet $\bigotimes_{i=1}^m \mathcal{U}_i \times \mathcal{X} \times \bigotimes_{i=1}^m \mathcal{Y}_i$. $\square$

Proof: Random code generation: For $\epsilon > 0$, $n > 0$ and $i \in [1, m]$, generate n -length sequences $\mathbf{u}_i(w_{i0})$, $w_{i0} \in \{0, 1, \dots, \lfloor 2^{n(I(U_i; Y_i) - \epsilon)} \rfloor - 1\}$, each with probability

$$P(\mathbf{u}_i) = \begin{cases} \frac{1}{\|A(U_i)\|}, & \mathbf{u}_i \in A(U_i) \\ 0, & \text{otherwise.} \end{cases} \quad (2)$$

where $\|A\|$ is the size of the set A . Also define bin $B_j^i := \{w_{i0} | w_{i0} \in [j \cdot \lfloor 2^{n(I(U_i; Y_i) - R_i - \epsilon)} \rfloor, (j+1) \cdot \lfloor 2^{n(I(U_i; Y_i) - R_i - \epsilon)} \rfloor - 1]\}$ for $j \in \{0, 1, \dots, \lfloor 2^{nR_i} \rfloor - 1\}$.

Encoding: To transmit a pair of messages $(w_1, \dots, w_m)$, pick a pair $(w_{10}, \dots, w_{m0}) \in \bigotimes_{i=1}^m B_{w_i}^i$ which satisfies $\mathbf{u}_S(w_{S0}) \in A(U_S) \forall S \subseteq \mathcal{B}$, $|S| > 1$, where $w_{S0} := \{w_{i0} | i \in S\}$. Such a $(w_{10}, \dots, w_{m0})$ exists with high probability if

$$\sum_{i \in S} R_i < \sum_{i \in S} (I(U_i; Y_i) - I(U_i; U_{S(i)})) - |S|\epsilon - \delta(\epsilon) \quad \forall S \subseteq \mathcal{B}, |S| > 1 \quad (3)$$

from Lemma 21 in the Appendix A. Then send an $\mathbf{x}$ which is jointly typical with $(\mathbf{u}_1(w_{10}), \dots, \mathbf{u}_m(w_{m0}))$.

Decoding: Receiver i decodes w_{i0} using jointly typical decoding of the sequence $(\mathbf{u}_i, \mathbf{y}_i)$.

Error analysis: We have the following error events :

E_{en} : there does not exist a pair $(w_{10}, \dots, w_{m0}) \in \bigotimes_{i=1}^m B_{w_i}^i$ such that $\mathbf{u}_S(w_{S0}) \in A(U_S)$, $\forall S \subseteq \mathcal{B}$, $|S| > 1$.

E_{emp} : $(\mathbf{u}_1(w_{10}), \dots, \mathbf{u}_m(w_{m0}), \mathbf{x}, \mathbf{y}_1, \dots, \mathbf{y}_m) \notin A(U_1 \dots U_m X Y_1 \dots Y_m)$.

E_i : there exists $\tilde{w}_{i0} \neq w_{i0}$ such that $(\mathbf{u}_{i0}(\tilde{w}_{i0}), \mathbf{y}_i) \in A(U_i Y_i)$.

Then,

$$P[E] \leq P[E_{\text{en}}] + P[E_{\text{emp}}] + \sum_{i=1}^m P[E_i] \quad (4)$$

$$\leq \epsilon' + \sum_{i=1}^m 2^{n(R_i - I(U_i; Y_i) + \epsilon)} \quad (5)$$

Since $\epsilon > 0$ is arbitrary, the conditions of Theorem 1 and the AEP property guarantee that the right hand sides of (5) as $n \rightarrow \infty$. $\blacksquare$

IV. ACHIEVABLE RATE REGIONS

We first derive achievable rate regions for the *simplest*, FMABC, PMABC, FTDBC, and PTDBC protocols using only conventional (for comparison) multiple access channel (MAC) and broadcast channel (BC) coding techniques - along the lines of Theorem 15.3.6 in [6] for the MAC and the extended Marton's region of Theorem 1 for the BC, as all protocols may be seen as combinations of MACs and BCs in the different phases. Due to their simplicity, the proofs for these simple cases are omitted and may be obtained as extensions of [14]–[16].

Subsequently, we ask whether these rate regions may be improved upon by using the more elaborate coding techniques which exploit over-heard side information and own-message side-information as previously described: network coding, random binning and user cooperation. We then obtain achievable rate regions for the different protocols using different combinations of encoding schemes. The proofs of the schemes are included in the Appendix.

A. Simplest Protocol

Theorem 2: An achievable rate region of the half-duplex bi-directional relay channel under the simplest protocol with decode and forward relaying is the closure of the set of all points $(R_{0,b}, R_{b,0})$ for all $b \in \mathcal{B}$ satisfying

$$R_{\{0\},\mathcal{B}} < \Delta_1 I(X_0^{(1)}; Y_r^{(1)}) \quad (6)$$

$$R_{i,0} < \Delta_{i+1} I(X_i^{(i+1)}; Y_r^{(i+1)}) \quad (7)$$

$$R_{\mathcal{B},\{0\}} < \Delta_{m+2} I(X_r^{(m+2)}; Y_0^{(m+2)}) \quad (8)$$

$$R_{0,i} < \Delta_{m+i+2} I(X_r^{(m+i+2)}; Y_i^{(m+i+2)}) \quad (9)$$

for $i \in \mathcal{B}$ over all joint distributions $\prod_{i=0}^m p^{(i+1)}(x_i) p^{(m+i+2)}(x_r)$, over the alphabet $\bigotimes_{i=0}^m \mathcal{X}_i \times \mathcal{X}_r$. $\square$

B. FMABC Protocol

Theorem 3: An achievable rate region of the half-duplex bi-directional relay channel under the FMABC protocol with decode and forward relaying is the closure of the set of all points $(R_{0,b}, R_{b,0})$ for all $b \in \mathcal{B}$ satisfying

$$R_{S,\mathcal{M}} < \Delta_1 I(X_S^{(1)}; Y_r^{(1)} | X_{\bar{S}}^{(1)}, Q) \quad (10)$$

$$R_{\mathcal{M},S} < \sum_{i \in S} \Delta_2 I(U_i^{(2)}; Y_i^{(2)}) - \Delta_2 I(U_i^{(2)}; U_{S(i)}^{(2)}) \quad (11)$$

for $S \subseteq \mathcal{M}$ over all joint distributions $p(q) \prod_{i=0}^m p^{(1)}(x_i|q)p^{(2)}(u_0, \dots, u_m, x_r)$, where U_j 's are the auxiliary random variables with $|\mathcal{Q}| \leq 2^{m+1} - 1$ over the alphabet $(\bigotimes_{i=0}^m \mathcal{X}_i \times \mathcal{U}_i) \times \mathcal{X}_r \times \mathcal{Q}$. $\square$

C. FMABC-N Protocol

We consider the FMABC protocol in which Network coding is employed at the relay to combine messages on a flow-by-flow basis - i.e. the message from node $i(\in \mathcal{B})$ to node 0 and vice-versa are combined at the relay. In the following theorem, the U_i variables are the auxiliary random variables similar to those seen in the extension of Marton's region of Theorem 1.

Theorem 4: An achievable rate region of the half-duplex bi-directional relay channel under the FMABC-N protocol with decode and forward relaying is the closure of the set of all points $(R_{0,b}, R_{b,0})$ for all $b \in \mathcal{B}$ satisfying

$$R_{S,\mathcal{M}} < \Delta_1 I(X_S^{(1)}; Y_r^{(1)} | X_{\bar{S}}^{(1)}, Q) \quad (12)$$

$$R_{\{0\},T} < \sum_{i \in T} \Delta_2 I(U_i^{(2)}; Y_i^{(2)}) - \Delta_2 I(U_i^{(2)}; U_{T(i)}^{(2)}) \quad (13)$$

$$R_{T,\{0\}} < \Delta_2 I(U_T^{(2)}; Y_0^{(2)}, U_{\bar{T}}^{(2)}) \quad (14)$$

for $S \subseteq \mathcal{M}$ and $T \subseteq \mathcal{B}$ over all joint distributions $p(q) \prod_{i=0}^m p^{(1)}(x_i|q)p^{(2)}(u_1, \dots, u_m, x_r)$, where U_j 's are the auxiliary random variables with $|\mathcal{Q}| \leq 2^{m+1} - 1$ over the alphabet $\bigotimes_{i=0}^m \mathcal{X}_i \times \bigotimes_{j=1}^m \mathcal{U}_j \times \mathcal{X}_r \times \mathcal{Q}$. $\square$

The rigorous proof is provided in Appendix B. We note that for the FMABC protocol only FMABC and FMABC-N (with network coding) are possible as there is no over-heard side information: during each phase every node is either transmitting or receiving - none are just listening. Hence, Random Binning and Cooperation schemes are impossible. Under the PMABC protocol however, Network Coding, Random Binning and Cooperation are all possible. We describe protocols with Network coding and Random binning, with and without Cooperation next.

D. PMABC Protocol

Theorem 5: An achievable rate region of the half-duplex bi-directional relay channel under the PMABC protocol with decode and forward relaying is the closure of the set of all points $(R_{0,b}, R_{b,0})$ for all $b \in \mathcal{B}$

satisfying

$$R_{0,i} < \Delta_i I(X_0^{(i)}; Y_r^{(i)} | X_i^{(i)}, Q) \quad (15)$$

$$R_{i,0} < \Delta_i I(X_i^{(i)}; Y_r^{(i)} | X_0^{(i)}, Q) \quad (16)$$

$$R_{0,i} + R_{i,0} < \Delta_i I(X_0^{(i)}, X_i^{(i)}; Y_r^{(i)} | Q) \quad (17)$$

$$R_{\mathcal{M},S} < \sum_{i \in S} \Delta_{m+1} I(U_i^{(m+1)}; Y_i^{(m+1)}) - \Delta_{m+1} I(U_i^{(m+1)}; U_{S(i)}^{(m+1)}) \quad (18)$$

for $i \in \mathcal{B}$ and $S \subseteq \mathcal{M}$ over all joint distributions $p(q) \prod_{i=1}^m p^{(i)}(x_0|q)p^{(i)}(x_i|q)p^{(m+1)}(u_0, \dots, u_m, x_r)$, where U_j 's are the auxiliary random variables with $|Q| \leq 3m$ over the alphabet $(\bigotimes_{i=0}^m \mathcal{X}_i \times \mathcal{U}_i) \times \mathcal{X}_r \times \mathcal{Q}$. $\square$

E. PMABC-NR Protocol

We consider the PMABC protocol in which Network coding is employed at the relay to combine messages on a flow-by-flow basis, along with Random Binning at the base-station node 0 to allow the end-nodes to exploit information over-heard in the phases during which they are not transmitting. In the following theorem, the U_i variables are the auxiliary random variables similar to those seen in the extension of Marton's region of Theorem 1, while V_{0i} are auxiliary random variables used for binning at the base-station node 0.

Theorem 6: An achievable rate region of the half-duplex bi-directional relay channel under the PMABC-NR protocol is the closure of the set of all points $(R_{0,b}, R_{b,0})$ for all $b \in \mathcal{B}$ satisfying

$$R_{\{0\},T} + R_{S,\{0\}} < \sum_{s \in S} \Delta_s I(V_{0T}^{(s)}, X_s^{(s)}; Y_r^{(s)}, V_{0T}^{(s)} | Q) + \sum_{s \in \bar{S}} \Delta_s I(V_{0T}^{(s)}; Y_r^{(s)}, V_{0T}^{(s)} | X_s^{(s)}, Q) \quad (19)$$

$$R_{\{0\},S} < \sum_{i \in S} \sum_{j=1}^m \left(\Delta_j I(V_{0i}^{(j)}; Y_i^{(j)} | Q) - \Delta_j I(V_{0i}^{(j)}; V_{0S(i)}^{(j)} | Q) \right) + \Delta_{m+1} I(U_i^{(m+1)}; Y_i^{(m+1)}) - \Delta_{m+1} I(U_i^{(m+1)}; U_{S(i)}^{(m+1)}) \quad (20)$$

$$R_{S,\{0\}} < \Delta_{m+1} I(U_S^{(m+1)}; Y_0^{(m+1)}, U_{\bar{S}}^{(m+1)}) \quad (21)$$

for all $S, T \subseteq \mathcal{B}$ over all joint distributions $p(q) \cdot [\prod_{i=1}^m p^{(i)}(v_{01}, \dots, v_{0m}, x_0|q)p^{(i)}(x_i|q)] \cdot p^{(m+1)}(u_1, \dots, u_m, x_r)$, where V_{0j} are the Random binning auxiliary random variables at node 0, U_j 's are the auxiliary Marton-like random variables used at node r and $V_{0T} := \{V_{0s} | s \in T\}$ with $|Q| \leq 2^{2m} + 2^m$ over the alphabet $\bigotimes_{i=0}^m \mathcal{X}_i \times \bigotimes_{j=1}^m (\mathcal{V}_{0j} \times \mathcal{U}_j) \times \mathcal{X}_r \times \mathcal{Q}$. $\square$

The rigorous proof is provided in Appendix C.

F. PMABC-NRC Protocol

We now allow the terminal nodes to *Cooperate* with each other in resolving the messages $w_{0,i}$, $\forall i \in \mathcal{B}$ - in addition to the flow-by-flow Network coding at the relay and the Random Binning at the base-station. In the following theorem:

- The U_i variables are the auxiliary random variables similar to those seen in the extension of Marton's region of Theorem 1.
- The V_{0i} are auxiliary random variables used for broadcasting at the base-station node 0.
- The V_{i1} are the auxiliary random variables for transmitting new information from node i to node 0.
- The V_{i2} are the auxiliary random variables for transmitting cooperative information from node i to other terminal nodes in the set $\mathcal{I}_i$, defined as the set of nodes which can decode $\hat{\mathbf{y}}_i^{(m+1)}(w_{\{i\},\mathcal{B}})$ at the end of transmission of node i . In a similar vein, $\mathcal{J}_i$ as the set of nodes whose quantized channel output is used at node i . Thus, $\mathcal{I}_i$ and $\mathcal{J}_i$ satisfy $\mathcal{I}_i = \{j | i \in \mathcal{J}_j, \forall j\}$. Note that we will derive achievable rate regions for *given* sets $\mathcal{I}_i$ and $\mathcal{J}_i$ and that the question of which sets are optimal will depend on the choice of metric, and are left open - in evaluating our bounds we union over all possible choices of these sets.

Theorem 7: An achievable rate region of the half-duplex bi-directional relay channel under the PMABC-NRC protocol is the closure of the set of all points $(R_{0,b}, R_{b,0})$ under given sets $\mathcal{I}_b$ and $\mathcal{J}_b$ for all $b \in \mathcal{B}$ satisfying

$$R_{\{0\},S} < \sum_{j=1}^m \Delta_j I(V_{0S}^{(j)}; Y_r^{(j)}, V_{0\bar{S}}^{(j)} | V_{j1}^{(j)}, Q) \quad (22)$$

$$R_{i,0} < \Delta_i I(V_{i1}^{(i)}; Y_r^{(i)} | Q) \quad (23)$$

$$R_{\{0\},S} < \sum_{i \in S} \left(\sum_{j \in \mathcal{J}_i} \Delta_j I(V_{0i}^{(j)}; Y_i^{(j)} | V_{j2}^{(j)}, Q) - \Delta_j I(V_{0i}^{(j)}; V_{0S(i)}^{(j)} | Q) + \sum_{j \notin \mathcal{J}_i} \Delta_j I(V_{0i}^{(j)}; Y_i^{(j)} | Q) - \Delta_j I(V_{0i}^{(j)}; V_{0S(i)}^{(j)} | Q) \right) + \Delta_{m+1} I(U_i^{(m+1)}; Y_i^{(m+1)}, \hat{Y}_{\mathcal{J}_i}^{(m+1)}) - \Delta_{m+1} I(U_i^{(m+1)}; U_{S(i)}^{(m+1)}) \quad (24)$$

$$R_{S,\{0\}} < \Delta_{m+1} I(U_S^{(m+1)}; Y_0^{(m+1)}, U_{\bar{S}}^{(m+1)}) \quad (25)$$

$$R_{i,0} < \Delta_i I(V_{i1}^{(i)}; Y_r^{(i)} | Q) + \Delta_i I(V_{i2}^{(i)}; Y_{\mathcal{I}_i}^{(i)} | Q) - \Delta_i I(V_{i1}^{(i)}; V_{i2}^{(i)} | Q) - \Delta_{m+1} I(Y_i^{(m+1)}; \hat{Y}_i^{(m+1)} | Y_{\mathcal{I}_i}^{(m+1)}) \quad (26)$$

subject to

$$\Delta_{m+1}I(Y_i^{(m+1)}; \hat{Y}_i^{(m+1)}|Y_j^{(m+1)}) < \Delta_i I(V_{i2}^{(i)}; Y_j^{(i)}|Q) \quad \text{for all } j \in \mathcal{I}_i \quad (27)$$

where $\mathcal{I}_i^{\min} = \operatorname{argmin}_{j \in \mathcal{I}_i} \{\Delta_i I(V_{i2}^{(i)}; Y_j^{(i)}|Q) - \Delta_{m+1}I(Y_i^{(m+1)}; \hat{Y}_i^{(m+1)}|Y_j^{(m+1)})\}$ for all $i \in \mathcal{B}$ over all joint distributions $p(q) \cdot (\prod_{i=1}^m p^{(i)}(v_{01}, \dots, v_{0m}, x_0|q) p^{(i)}(v_{i1}, v_{i2}, x_i|q)) \cdot p^{(m+1)}(u_1, \dots, u_m, x_r) \cdot p^{(m+1)}(y_B|x_r) \cdot (\prod_{i=1}^m p^{(m+1)}(\hat{y}_i|y_i))$, where $V_{0i}, V_{i1}, V_{i2}, U_i$'s are the auxiliary random variables and $V_{0T} := \{V_{0s}|s \in T\}$ with $|Q| \leq 2^{m+1} + m^2 + m + 2$ over the alphabet $\bigotimes_{i=0}^m \mathcal{X}_i \times \bigotimes_{j=1}^m (\mathcal{V}_{0j} \times \mathcal{V}_{j1} \times \mathcal{V}_{j2} \times \mathcal{U}_j) \times \mathcal{X}_r \times \mathcal{Q}$. $\square$

Remark 8: (22) and (23) result from the multiple access period ³, while (24) and (25) result from the relay broadcast period. Also, (26) and (27) result from the cooperation between terminal nodes. The rigorous proof is provided in Appendix D.

G. FTDBC Protocol

Theorem 9: An achievable rate region of the half-duplex bi-directional relay channel under the FTDBC protocol with decode and forward relaying is the closure of the set of all points $(R_{0,b}, R_{b,0})$ for all $b \in \mathcal{B}$ satisfying

$$R_{\{0\}, \mathcal{B}} < \Delta_1 I(X_0^{(1)}; Y_r^{(1)}) \quad (28)$$

$$R_{i,0} < \Delta_{i+1} I(X_i^{(i+1)}; Y_r^{(i+1)}) \quad (29)$$

$$R_{\mathcal{M}, S} < \sum_{i \in S} \Delta_{m+2} I(U_i^{(m+2)}; Y_i^{(m+2)}) - \Delta_{m+2} I(U_i^{(m+2)}; U_{S(i)}^{(m+2)}) \quad (30)$$

for $i \in \mathcal{B}$ and $S \subseteq \mathcal{M}$ over all joint distributions $\prod_{i=0}^m p^{(i+1)}(x_i) p^{(m+2)}(u_0, \dots, u_m, x_r)$, where U_j 's are the auxiliary random variables over the alphabet $(\bigotimes_{i=0}^m \mathcal{X}_i \times \mathcal{U}_i) \times \mathcal{X}_r$. $\square$

H. FTDBC-NR Protocol

We next consider the FTDBC protocol in which Network coding is employed at the relay to combine messages on a flow-by-flow basis, along with Random Binning at the base-station node 0 to allow the end-nodes to exploit information over-heard in the phases during which they are not transmitting. In the following theorem, the U_i variables are the auxiliary random variables similar to those seen in the extension of Marton's region of Theorem 1, while V_{0i} are auxiliary random variables used for broadcasting at the base-station node 0.

³(22) and (23) are suboptimal for multiple access channel. Generally this is the channel in which two transmitters are simultaneously broadcasting to multiple receivers. We introduce a simpler suboptimal scheme here and leave the optimization for the future work.

Fig. 5. A diagram of encoders in the FTDBC-NR protocol with $\frac{1}{n} \log L_{0i} = \Delta_1 I(V_{0i}^{(1)}; Y_i^{(1)}) + R_{0,i:1} - R_{0,i}$, $\frac{1}{n} \log H_{0,i} = R_{0,i}$, $\frac{1}{n} \log L_{ri} = \Delta_{m+2} I(U_i^{(m+2)}; Y_i^{(m+2)}) - R_{0,i:1}$ and $\frac{1}{n} \log H_{ri} = \max\{R_{0,i:1}, R_{i,0:1}\}$ for all $i \in [1, m]$. Also, $B_{w_{0,i}}^i$ is the subset (bin) of the set $\{w_{0,i:2}\}$ indexed by $w_{0,i}$. Similarly, $C_{w_i}^i$ is the subset (bin) of the set $\{w_{ri}\}$ indexed by w_i .

Theorem 10: An achievable rate region of the half-duplex bi-directional relay channel under the FTDBC-NR protocol is the closure of the set of all points $(R_{0,b}, R_{b,0})$ for all $b \in \mathcal{B}$ satisfying

$$R_{\{0\},S} < \Delta_1 I(V_{0S}^{(1)}; Y_r^{(1)}, V_{0\bar{S}}^{(1)}) \quad (31)$$

$$R_{i,0} < \Delta_{i+1} I(X_i^{(i+1)}; Y_r^{(i+1)}) \quad (32)$$

$$R_{\{0\},S} < \sum_{i \in S} \Delta_1 I(V_{0i}^{(1)}; Y_i^{(1)}) - \Delta_1 I(V_{0i}^{(1)}; V_{0S(i)}^{(1)}) +$$

$$\Delta_{m+2}I(U_i^{(m+2)}; Y_i^{(m+2)}) - \Delta_{m+2}I(U_i^{(m+2)}; U_{S(i)}^{(m+2)}) \quad (33)$$

$$R_{S,\{0\}} < \sum_{i \in S} \Delta_{i+1}I(X_i^{(i+1)}; Y_0^{(i+1)}) + \Delta_{m+2}I(U_S^{(m+2)}; Y_0^{(m+2)}, U_{\bar{S}}^{(m+2)}) \quad (34)$$

for all $i \in \mathcal{B}$ and $S \subseteq \mathcal{B}$ over all joint distributions $p^{(1)}(v_{01}, \dots, v_{0m}, x_0) \cdot \left(\prod_{j=1}^m p^{(j+1)}(x_j) \right) \cdot p^{(m+2)}(u_1, \dots, u_m, x_r)$, where V_{0j}, U_j 's are the auxiliary random variables and $V_{0T} := \{V_{0s} | s \in T\}$ over the alphabet $\bigotimes_{i=0}^m \mathcal{X}_i \times \bigotimes_{j=1}^m (\mathcal{V}_{0j} \times \mathcal{U}_j) \times \mathcal{X}_r$. $\square$

Remark 11: (31) and (32) correspond to the transmissions from $\mathcal{M}$ to the relay r , while (33) – (34) correspond to the relay broadcast phase. An example of the encoding is provided in Fig. 5, where we see the different auxiliary random variables at nodes 0, i and the relay r . The rigorous proof is provided in Appendix E.

I. FTDBC-NRC protocol

We allow the terminal nodes to *Cooperate* with each other in resolving the messages $w_{0,i}$, $\forall i \in \mathcal{B}$ - in addition to the flow-by-flow Network coding at the relay and the Random Binning at the base-station. In the following theorem the interpretations of the auxiliary random variables $U_i, V_{0i}, V_{i1}, V_{i2}$ are the same as those of Theorem 7.

Theorem 12: An achievable rate region of the half-duplex bi-directional relay channel under the FTDBC-NRC protocol is the closure of the set of all points $(R_{0,b}, R_{b,0})$ under given sets $\mathcal{I}_b$ and $\mathcal{J}_b$ for all $b \in \mathcal{B}$ satisfying

$$R_{\{0\},S} < \Delta_1 I(V_{0S}^{(1)}; Y_r^{(1)}, V_{0\bar{S}}^{(1)}) \quad (35)$$

$$R_{i,0} < \Delta_{i+1} I(V_{i1}^{(i+1)}; Y_r^{(i+1)}) \quad (36)$$

$$R_{\{0\},S} < \sum_{i \in S} \Delta_1 I(V_{0i}^{(1)}; Y_i^{(1)}) - \Delta_1 I(V_{0i}^{(1)}; V_{0S(i)}^{(1)}) + \Delta_{m+2} I(U_i^{(m+2)}; Y_i^{(m+2)}, \hat{Y}_{\mathcal{J}_i}^{(m+2)}) - \Delta_{m+2} I(U_i^{(m+2)}; U_{S(i)}^{(m+2)}) \quad (37)$$

$$R_{S,\{0\}} < \sum_{i \in S} \Delta_{i+1} I(V_{i1}^{(i+1)}; Y_0^{(i+1)}) + \Delta_{m+2} I(U_S^{(m+2)}; Y_0^{(m+2)}, U_{\bar{S}}^{(m+2)}) \quad (38)$$

$$R_{i,0} < \Delta_{i+1} I(V_{i1}^{(i+1)}; Y_r^{(i+1)}) + \Delta_{i+1} I(V_{i2}^{(i+1)}; Y_{\mathcal{I}_i^{\min}}^{(i+1)}) - \Delta_{i+1} I(V_{i1}^{(i+1)}; V_{i2}^{(i+1)}) - \Delta_{m+2} I(Y_i^{(m+2)}; \hat{Y}_i^{(m+2)} | Y_{\mathcal{I}_i^{\min}}^{(m+2)}) \quad (39)$$

subject to

$$\Delta_{m+2} I(Y_i^{(m+2)}; \hat{Y}_i^{(m+2)} | Y_j^{(m+2)}) < \Delta_{i+1} I(V_{i2}^{(i+1)}; Y_j^{(i+1)}) \quad \text{for all } j \in \mathcal{I}_i \quad (40)$$

where $\mathcal{I}_i^{\min} = \operatorname{argmin}_{j \in \mathcal{I}_i} \{\Delta_{i+1}I(V_{i2}^{(i+1)}; Y_j^{(i+1)}) - \Delta_{m+2}I(Y_i^{(m+2)}; \hat{Y}_i^{(m+2)} | Y_j^{(m+2)})\}$ for all $i \in \mathcal{B}$ and $S \subseteq \mathcal{B}$ over all joint distributions $p^{(1)}(v_{01}, \dots, v_{0m}, x_0) \prod_{j=1}^m p^{(j+1)}(v_{j1}, v_{j2}, x_j) p^{(m+2)}(u_1, \dots, u_m, x_r) p^{(m+2)}(y_{\mathcal{B}} | x_r) \cdot \prod_{k=1}^m p^{(m+2)}(\hat{y}_k | y_k)$, where $V_{0j}, V_{j1}, V_{j2}, U_j$'s are the auxiliary random variables and $V_{0T} := \{V_{0s} | s \in T\}$ over the alphabet $\bigotimes_{i=0}^m \mathcal{X}_i \times \bigotimes_{j=1}^m (\mathcal{V}_{0j} \times \mathcal{V}_{j1} \times \mathcal{V}_{j2} \times \mathcal{U}_j) \times \mathcal{X}_r$. $\square$

Proof outline : The proof of Theorem 12 follows the same argument as the proof of Theorem 3 in [16] and Theorem 7.

J. PTDBC Protocol

Theorem 13: An achievable rate region of the half-duplex bi-directional relay channel under the PTDBC protocol with decode and forward relaying is the closure of the set of all points $(R_{0,b}, R_{b,0})$ for all $b \in \mathcal{B}$ satisfying

$$R_{\{0\}, \mathcal{B}} < \Delta_1 I(X_0^{(1)}; Y_r^{(1)}) \quad (41)$$

$$R_{T, \{0\}} < \Delta_2 I(X_T^{(2)}; Y_r^{(2)} | X_{\bar{T}}^{(2)}, Q) \quad (42)$$

$$R_{\mathcal{M}, S} < \sum_{i \in S} \Delta_3 I(U_i^{(3)}; Y_i^{(3)}) - \Delta_3 I(U_i^{(3)}; U_{S(i)}^{(3)}) \quad (43)$$

for $S \subseteq \mathcal{M}$ and $T \subseteq \mathcal{B}$ over all joint distributions $p(q)p^{(1)}(x_0|q) \prod_{i=1}^m p^{(2)}(x_i|q)p^{(3)}(u_0, \dots, u_m, x_r)$, where U_j 's are the auxiliary random variables with $|\mathcal{Q}| \leq 2^m - 1$ over the alphabet $(\bigotimes_{i=0}^m \mathcal{X}_i \times \mathcal{U}_i) \times \mathcal{X}_r \times \mathcal{Q}$. $\square$

K. PTDBC-NR Protocol

We next consider the PTDBC protocol in which Network coding is employed at the relay to combine messages on a flow-by-flow basis, along with Random Binning at the base-station node 0 to allow the end-nodes to exploit information over-heard in the phases during which they are not transmitting.

Theorem 14: An achievable rate region of the half-duplex bi-directional relay channel under the PTDBC-NR protocol is the closure of the set of all points $(R_{0,b}, R_{b,0})$ for all $b \in \mathcal{B}$ satisfying

$$R_{\{0\}, S} < \Delta_1 I(V_{0S}^{(1)}; Y_r^{(1)}, V_{0\bar{S}}^{(1)}) \quad (44)$$

$$R_{S, \{0\}} < \Delta_2 I(X_S^{(2)}; Y_r^{(2)} | X_{\bar{S}}^{(2)}, Q) \quad (45)$$

$$R_{\{0\}, S} < \sum_{i \in S} \Delta_1 I(V_{0i}^{(1)}; Y_i^{(1)}) - \Delta_1 I(V_{0i}^{(1)}; V_{0S(i)}^{(1)}) + \Delta_3 I(U_i^{(3)}; Y_i^{(3)}) - \Delta_3 I(U_i^{(3)}; U_{S(i)}^{(3)}) \quad (46)$$

$$R_{S, \{0\}} < \Delta_2 I(X_S^{(2)}; Y_0^{(2)} | X_{\bar{S}}^{(2)}, Q) + \Delta_3 I(U_S^{(3)}; Y_0^{(3)}, U_{\bar{S}}^{(3)}) \quad (47)$$

for all $S \subseteq \mathcal{B}$ over all joint distributions $p(q)p^{(1)}(v_{01}, \dots, v_{0m}, x_0) \cdot \left(\prod_{j=1}^m p^{(2)}(x_j|q)\right) \cdot p^{(3)}(u_1, \dots, u_m, x_r)$, where V_{0j}, U_j 's are the auxiliary random variables and $V_{0T} := \{V_{0s}|s \in T\}$ with $|\mathcal{Q}| \leq 2^m - 1$ over the alphabet $\bigotimes_{i=0}^m \mathcal{X}_i \times \bigotimes_{j=1}^m (\mathcal{V}_{0j} \times \mathcal{U}_j) \times \mathcal{X}_r \times \mathcal{Q}$. $\square$

Remark 15: (44) and (45) correspond to the transmissions from $\mathcal{M}$ to the relay r , while (46) – (47) correspond to the relay broadcast phase. The proof of Theorem 14 follows the same argument as the proof of Theorem 3 in [16] and Theorem 6.

V. OUTER BOUNDS

We now derive outer bounds for the FMABC, PMABC, FTDBC and PTDBC protocols using the following cut-set bound lemma tailored to multi-phase protocols first derived in [16], and included for completeness. Given subsets $S, T \subseteq \mathcal{M} = \{1, 2, \dots, m\}$, and $\bar{S} := \mathcal{M} \setminus S$, we define $W_{S,T} := \{W_{i,j}|i \in S, j \in T\}$ and $R_{S,T} = \lim_{n \rightarrow \infty} \frac{1}{n} H(W_{S,T})$.

Lemma 16: If in some network the information rates $\{R_{i,j}\}$ are achievable for a protocol P with relative phase durations $\{\Delta_\ell\}$, then for every $\epsilon > 0$ and all $S \subset \mathcal{M}$

$$R_{S,\bar{S}} \leq \sum_{\ell} \Delta_{\ell} I(X_S^{(\ell)}; Y_{\bar{S}}^{(\ell)} | X_{\bar{S}}^{(\ell)}, Q) + \epsilon, \quad (48)$$

for a family of conditional distributions $p^{(\ell)}(x_1, x_2, \dots, x_m|q)$ and a discrete time-sharing random variable Q with distribution $p(q)$. Furthermore, each $p^{(\ell)}(x_1, x_2, \dots, x_m|q)p(q)$ must satisfy the constraints of phase ℓ of protocol P . $\square$

The FMABC, PMABC, FTDBC and PTDBC outer bounds are obtained by applying the above lemma to the different protocols; in each protocol the “cuts” will look different depending on what nodes are permitted to transmit during each phase, leading to different outer bound regions.

A. FMABC protocol

Theorem 17: (Outer bound) The capacity region of the half-duplex bi-directional relay channel under the FMABC protocol is outer bounded by the set of all points $(R_{0,b}, R_{b,0})$ for all $b \in \mathcal{B}$ satisfying

$$R_{\{0\},\mathcal{B}} \leq \Delta_1 I(X_0^{(1)}; Y_r^{(1)} | X_B^{(1)}, Q) \quad (49)$$

$$R_{\mathcal{B},\{0\}} \leq \Delta_2 I(X_r^{(2)}; Y_0^{(2)}) \quad (50)$$

$$R_{S,\{0\}} \leq \Delta_1 I(X_S^{(1)}; Y_r^{(1)} | X_{\bar{S}}^{(1)}, X_0^{(1)}, Q) \quad (51)$$

$$R_{\{0\},S} \leq \Delta_2 I(X_r^{(2)}; Y_S^{(2)}) \quad (52)$$

for all choices of the joint distribution $p(q) \prod_{i=0}^m p^{(1)}(x_i|q) p^{(2)}(x_r)$ with $|\mathcal{Q}| \leq 2^m$ over the restricted alphabet $\bigotimes_{i=0}^m \mathcal{X}_i \times \mathcal{X}_r \times \mathcal{Q}$ for all possible $S \subseteq \mathcal{B}$. $\square$

Proof: For every $S \subseteq \mathcal{B}$, there exist 4 types of cut-sets: $S_1 = \{0\} \cup S$, $S_2 = \{r\} \cup S$, $S_3 = \{0, r\} \cup S$ and $S_4 = S$, with corresponding rate pairs $R_{S, \{0\}}$ and $R_{\{0\}, S}$. By definition of the FMABC protocol,

$$Y_{\mathcal{M}}^{(1)} = X_r^{(1)} = \emptyset \quad (53)$$

$$X_{\mathcal{M}}^{(2)} = Y_r^{(2)} = \emptyset. \quad (54)$$

Thus, the corresponding outer bounds for a given subset S are:

$$S_1 : R_{\{0\}, \bar{S}} \leq \Delta_1 I(X_0^{(1)}, X_S^{(1)}; Y_r^{(1)} | X_{\bar{S}}^{(1)}, Q) + \epsilon, \quad (55)$$

$$S_2 : R_{S, \{0\}} \leq \Delta_2 I(X_r^{(2)}; Y_0^{(2)}, Y_{\bar{S}}^{(2)}) + \epsilon, \quad (56)$$

$$S_3 : R_{\{0\}, \bar{S}} \leq \Delta_2 I(X_r^{(2)}; Y_{\bar{S}}^{(2)}) + \epsilon, \quad (57)$$

$$S_4 : R_{S, \{0\}} \leq \Delta_1 I(X_S^{(1)}; Y_r^{(1)} | X_{\bar{S}}^{(1)}, X_0^{(1)}, Q) + \epsilon, \quad (58)$$

In (55), we have

$$R_{\{0\}, \bar{S}} \leq R_{\{0\}, \mathcal{B}} \quad (59)$$

$$\leq \Delta_1 I(X_0^{(1)}; Y_r^{(1)} | X_{\mathcal{B}}^{(1)}, Q) + \epsilon \quad (60)$$

$$= \Delta_1 I(X_0^{(1)}; Y_r^{(1)} | X_S^{(1)}, X_{\bar{S}}^{(1)}, Q) + \epsilon \quad (61)$$

$$\leq \Delta_1 I(X_0^{(1)}, X_S^{(1)}; Y_r^{(1)} | X_{\bar{S}}^{(1)}, Q) + \epsilon \quad (62)$$

Similarly, in (56), we have

$$R_{S, \{0\}} \leq R_{\mathcal{B}, \{0\}} \quad (63)$$

$$\leq \Delta_2 I(X_r^{(2)}; Y_0^{(2)}) + \epsilon \quad (64)$$

$$\leq \Delta_2 I(X_r^{(2)}; Y_0^{(2)}, Y_{\bar{S}}^{(2)}) + \epsilon \quad (65)$$

Thus, the following inequalities capture all possible S_1 's and S_2 's, respectively.

$$R_{\{0\}, \mathcal{B}} \leq \Delta_1 I(X_0^{(1)}; Y_r^{(1)} | X_{\mathcal{B}}^{(1)}, Q) + \epsilon \quad (66)$$

$$R_{\mathcal{B}, \{0\}} \leq \Delta_2 I(X_r^{(2)}; Y_0^{(2)}) + \epsilon \quad (67)$$

Since $\epsilon > 0$ is arbitrary, (58), (66), (67) and (57) yield Theorem 17. By Fenchel-Bunt's extension of the Carathéodory theorem in [12], it is sufficient to restrict $|\mathcal{Q}| \leq 2^m$. $\blacksquare$

B. PMABC protocol

Theorem 18: (Outer bound) The capacity region of the half-duplex bi-directional relay channel under the PMABC protocol is outer bounded by the set of all points $(R_{0,b}, R_{b,0})$ for all $b \in \mathcal{B}$ satisfying

$$R_{\{0\},\mathcal{B}} \leq \sum_{i=1}^m \Delta_i I(X_0^{(i)}; Y_r^{(i)} | X_i^{(i)}, Q) \quad (68)$$

$$R_{\mathcal{B},\{0\}} \leq \Delta_{m+1} I(X_r^{(m+1)}; Y_0^{(m+1)}) \quad (69)$$

$$R_{S,\{0\}} \leq \sum_{i \in S} \Delta_i I(X_i^{(i)}; Y_r^{(i)}, Y_{\bar{S}}^{(i)} | X_0^{(i)}, Q) \quad (70)$$

$$R_{\{0\},S} \leq \sum_{i \in \bar{S}} \Delta_i I(X_0^{(i)}, X_i^{(i)}; Y_S^{(i)} | Q) + \sum_{i \in S} \Delta_i I(X_0^{(i)}; Y_{S \setminus \{i\}}^{(i)} | X_i^{(i)}, Q) + \Delta_{m+1} I(X_r^{(m+1)}; Y_S^{(m+1)}) \quad (71)$$

for all choices of the joint distribution $p(q) \prod_{i=1}^m p^{(i)}(x_0|q)p^{(i)}(x_i|q)p^{(m+1)}(x_r)$ with $|\mathcal{Q}| \leq 2^{m+1} - 1$ over the restricted alphabet $\bigotimes_{i=0}^m \mathcal{X}_i \times \mathcal{X}_r \times \mathcal{Q}$ for all possible $S \subseteq \mathcal{B}$. $\square$

Proof outline : The proof of Theorem 18 follows the same argument as the proof of Theorem 17.

C. FTDBC protocol

Theorem 19: (Outer bound) The capacity region of the half-duplex bi-directional relay channel under the FTDBC protocol is outer bounded by the set of all points $(R_{0,b}, R_{b,0})$ for all $b \in \mathcal{B}$ satisfying

$$R_{\{0\},S} \leq \min \left\{ \Delta_1 I(X_0^{(1)}; Y_r^{(1)}, Y_S^{(1)}) + \sum_{i \in \bar{S}} \Delta_{i+1} I(X_i^{(i+1)}; Y_r^{(i+1)}, Y_S^{(i+1)}), \right. \\ \left. \Delta_1 I(X_0^{(1)}; Y_S^{(1)}) + \sum_{i \in \bar{S}} \Delta_{i+1} I(X_i^{(i+1)}; Y_S^{(i+1)}) + \Delta_{m+2} I(X_r^{(m+2)}; Y_S^{(m+2)}) \right\} \quad (72)$$

$$R_{S,\{0\}} \leq \min \left\{ \sum_{i \in S} \Delta_{i+1} I(X_i^{(i+1)}; Y_0^{(i+1)}, Y_{\bar{S}}^{(i+1)}) + \Delta_{m+2} I(X_r^{(m+2)}; Y_0^{(m+2)}, Y_{\bar{S}}^{(m+2)}), \right. \\ \left. \sum_{i \in S} \Delta_{i+1} I(X_i^{(i+1)}; Y_0^{(i+1)}, Y_{\bar{S}}^{(i+1)}, Y_r^{(i+1)}) \right\} \quad (73)$$

for all choices of the joint distribution $\prod_{i=0}^m p^{(i+1)}(x_i) p^{(m+2)}(x_r)$ over the restricted alphabet $\bigotimes_{i=0}^m \mathcal{X}_i \times \mathcal{X}_r$ for all possible $S \subseteq \mathcal{B}$. $\square$

Proof outline : The proof of Theorem 19 follows the same argument as the proof of Theorem 17.

D. PTDBC protocol

Theorem 20: (Outer bound) The capacity region of the half-duplex bi-directional relay channel under the PTDBC protocol is outer bounded by the set of all points $(R_{0,b}, R_{b,0})$ for all $b \in \mathcal{B}$ satisfying

$$R_{\{0\},S} \leq \min \left\{ \Delta_1 I(X_0^{(1)}; Y_r^{(1)}, Y_S^{(1)}) + \Delta_2 I(X_{\bar{S}}^{(2)}; Y_r^{(2)} | X_S^{(2)}, Q), \right. \\ \left. \Delta_1 I(X_0^{(1)}; Y_S^{(1)}) + \Delta_3 I(X_r^{(3)}; Y_S^{(3)}) \right\} \quad (74)$$

$$R_{S,\{0\}} \leq \min \left\{ \Delta_2 I(X_S^{(2)}; Y_0^{(2)} | X_{\bar{S}}^{(2)}, Q) + \Delta_3 I(X_r^{(2)}; Y_0^{(2)}, Y_{\bar{S}}^{(2)}), \right. \\ \left. \Delta_2 I(X_S^{(2)}; Y_0^{(2)}, Y_r^{(2)} | X_{\bar{S}}^{(2)}, Q) \right\} \quad (75)$$

for all choices of the joint distribution $p(q)p^{(1)}(x_0) \prod_{i=1}^m p^{(2)}(x_i|q) p^{(3)}(x_r)$ with $|\mathcal{Q}| \leq 2^m - 1$ over the restricted alphabet $\bigotimes_{i=0}^m \mathcal{X}_i \times \mathcal{X}_r \times \mathcal{Q}$ for all possible $S \subseteq \mathcal{B}$. $\square$

Proof outline : The proof of Theorem 20 follows the same argument as the proof of Theorem 17.

These outer bounds will be evaluated in Gaussian noise, as described next.

VI. GAUSSIAN NOISE CHANNEL

In this section, we evaluate the achievable rate regions and outer bounds obtained in the previous section to an AWGN channel. To do so, we assume an additive white Gaussian noise (AWGN) channel model, assume Gaussian input distributions for the achievability schemes, which may or may not be optimal, and evaluate the mutual information terms. The resulting rate regions are indeed quite complex: our goals are to demonstrate, at least under Gaussian input distributions, that:

- Network coding, Random Binning, and Cooperation all improve the rate regions over simpler schemes which employ standard multiple access and broadcast channel coding schemes.
- There are no inclusion relationships between FMABC, PMABC, FTDBC and PTDBC regions.

Furthermore, we include entirely the somewhat laborious analytical expressions in the Gaussian noise regime; we hope that these expressions may be of use to the further exploration of the obtained regions in for example the high or low SNR regimes, which is the subject of current investigation [20].

A. Channel model

The corresponding mathematical channel model is, for each channel use k :

$$\mathbf{Y}[k] = \mathbf{H}\mathbf{X}[k] + \mathbf{Z}[k] \quad (76)$$

where,

$$\mathbf{Y}[k] = \begin{bmatrix} Y_0[k] \\ Y_1[k] \\ \vdots \\ Y_m[k] \\ Y_r[k] \end{bmatrix}, \quad \mathbf{X}[k] = \begin{bmatrix} X_0[k] \\ X_1[k] \\ \vdots \\ X_m[k] \\ X_r[k] \end{bmatrix}, \quad \mathbf{Z}[k] = \begin{bmatrix} Z_0[k] \\ Z_1[k] \\ \vdots \\ Z_m[k] \\ Z_r[k] \end{bmatrix} \quad (77)$$

and

$$\mathbf{H} = \begin{bmatrix} 0 & h_{0,1} & \cdots & h_{0,r} \\ h_{1,0} & 0 & \cdots & h_{1,r} \\ \vdots & \ddots & \vdots & \vdots \\ h_{r,0} & h_{r,1} & \cdots & 0 \end{bmatrix} \quad (78)$$

where $\mathbf{Y}[k]$, $\mathbf{X}[k]$ and $\mathbf{Z}[k]$ are in $(\mathbb{C}^*)^{(m+2) \times 1} = (\mathbb{C} \cup \{\emptyset\})^{(m+2) \times 1}$, and $\mathbf{H} \in \mathbb{C}^{(m+2) \times (m+2)}$. In phase ℓ , if node i is in transmission mode $X_i[k]$ follows the input distribution $X_i^{(\ell)} \sim \mathcal{CN}(0, P_i)$. Otherwise, $X_i[k] = \emptyset$, which means that the input symbol does not exist in the above mathematical channel model.

$h_{i,j}$ is the effective channel gain between transmitter i and receiver j . We assume that each node is fully aware of the channel gains, i.e., full CSI. The noise at all receivers is independent, of unit power, additive, white Gaussian, complex and circularly symmetric. For convenience of analysis, we also define the function $C(x) := \log_2(1 + x)$.

For the simplest case $m = 2$, we get the following achievable rate regions for the Gaussian channel from Theorems 3 ~ 14. For the analysis of the cooperation scheme, we assume $\hat{Y}_1$ are zero mean Gaussians and define $P_y := E[Y_1^2]$, $P_{\hat{y}} := E[\hat{Y}_1^2]$ and $\sigma_y := E[\hat{Y}_1 Y_1]$. Then the relation between the received Y_1 and the compressed $\hat{Y}_1$ are given by the following equivalent channel model:

$$\hat{Y}_1[k] = h_{1\hat{1}} Y_1[k] + Z_{\hat{1}}[k] \quad (79)$$

where $h_{1\hat{1}} = \frac{\sigma_y}{P_y}$ and $Z_{\hat{1}} \sim \mathcal{CN}(0, P_{\hat{y}} - \frac{\sigma_y^2}{P_y})$. We note that in the following, $P_{\hat{y}}$ and σ_y are unknown variables corresponding to the quantization which we numerically optimize. For convenience of analysis, we assume that $|h_{r,1}| > |h_{r,2}|$, $|h_{0,1}| > |h_{0,2}|$ and $|h_{1,r}| > |h_{1,2}|$. Since the given channel is degraded as $X_r \rightarrow Y_1 \rightarrow Y_2$, $\mathcal{I}_1 = \{2\}$ and $\mathcal{I}_2 = \emptyset$.

B. Achievable rate regions in the Gaussian channel with $m = 2$

We apply the bounds found in previous sections to the Gaussian channel with three terminal nodes (0, 1, 2) and one relay node (r). The detail evaluations of necessary mutual information terms are defined in Appendix F.

- Simplest Protocol

$$\text{From (6)} \left\{ \begin{array}{l} R_{0,1} + R_{0,2} < \Delta_1 C(|h_{0,r}|^2 P_0) \end{array} \right. \quad (80)$$

$$\text{From (7)} \left\{ \begin{array}{l} R_{1,0} < \Delta_2 C(|h_{1,r}|^2 P_1) \\ R_{2,0} < \Delta_3 C(|h_{2,r}|^2 P_2) \end{array} \right. \quad (81)$$

$$\text{From (8)} \left\{ \begin{array}{l} R_{1,0} + R_{2,0} < \Delta_4 C(|h_{r,0}|^2 P_r) \end{array} \right. \quad (82)$$

$$\text{From (9)} \left\{ \begin{array}{l} R_{0,1} < \Delta_5 C(|h_{r,1}|^2 P_r) \\ R_{0,2} < \Delta_6 C(|h_{r,2}|^2 P_r) \end{array} \right. \quad (83)$$

To obtain the regions numerically, we optimize Δ_1 , Δ_2 , Δ_3 , Δ_4 , Δ_5 and Δ_6 for the given channel mutual informations to maximize the achievable rate regions.

- FMABC Protocol

$$\text{From (10)} \left\{ \begin{array}{l} R_{0,1} + R_{0,2} < \Delta_1 C(|h_{0,r}|^2 P_0) \\ R_{1,0} < \Delta_1 C(|h_{1,r}|^2 P_1) \\ R_{2,0} < \Delta_1 C(|h_{2,r}|^2 P_2) \\ R_{0,1} + R_{0,2} + R_{1,0} < \Delta_1 C(|h_{0,r}|^2 P_0 + |h_{1,r}|^2 P_1) \\ R_{0,1} + R_{0,2} + R_{2,0} < \Delta_1 C(|h_{0,r}|^2 P_0 + |h_{2,r}|^2 P_2) \\ R_{1,0} + R_{2,0} < \Delta_1 C(|h_{1,r}|^2 P_1 + |h_{2,r}|^2 P_2) \\ R_{0,1} + R_{0,2} + R_{1,0} + R_{2,0} < \Delta_1 C(|h_{0,r}|^2 P_0 + |h_{1,r}|^2 P_1 + |h_{2,r}|^2 P_2) \end{array} \right. \quad (84)$$

$$\text{From (11)} \left\{ \begin{array}{l} R_{1,0} + R_{2,0} < \Delta_2 C_B(P_r, h_{r,0}, \bar{\lambda}_{r1}^{(2)}, \bar{\beta}_r^{(2)}) \\ R_{0,1} < \Delta_2 C_B(P_r, h_{r,0}, \bar{\lambda}_{r2}^{(2)}, \bar{\beta}_r^{(2)}) \\ R_{0,2} < \Delta_2 C_B(P_r, h_{r,0}, \bar{\lambda}_{r3}^{(2)}, \bar{\beta}_r^{(2)}) \\ R_{1,0} + R_{2,0} + R_{0,1} < \Delta_2 (C_B(P_r, h_{r,0}, \bar{\lambda}_{r1}^{(2)}, \bar{\beta}_r^{(2)}) + C_B(P_r, h_{r,0}, \bar{\lambda}_{r2}^{(2)}, \bar{\beta}_r^{(2)}) - \Delta_2 C_{BE}(\bar{\lambda}_{r1}^{(2)}, \bar{\lambda}_{r2}^{(2)}, \bar{\beta}_r^{(2)})) \\ R_{1,0} + R_{2,0} + R_{0,2} < \Delta_2 (C_B(P_r, h_{r,0}, \bar{\lambda}_{r1}^{(2)}, \bar{\beta}_r^{(2)}) + C_B(P_r, h_{r,0}, \bar{\lambda}_{r3}^{(2)}, \bar{\beta}_r^{(2)}) - \Delta_2 C_{BE}(\bar{\lambda}_{r1}^{(2)}, \bar{\lambda}_{r3}^{(2)}, \bar{\beta}_r^{(2)})) \\ R_{0,1} + R_{0,2} < \Delta_2 (C_B(P_r, h_{r,0}, \bar{\lambda}_{r2}^{(2)}, \bar{\beta}_r^{(2)}) + C_B(P_r, h_{r,0}, \bar{\lambda}_{r3}^{(2)}, \bar{\beta}_r^{(2)}) - \Delta_2 C_{BE}(\bar{\lambda}_{r2}^{(2)}, \bar{\lambda}_{r3}^{(2)}, \bar{\beta}_r^{(2)})) \\ R_{1,0} + R_{2,0} + R_{0,1} + R_{0,2} < \Delta_2 (C_B(P_r, h_{r,0}, \bar{\lambda}_{r1}^{(2)}, \bar{\beta}_r^{(2)}) + C_B(P_r, h_{r,0}, \bar{\lambda}_{r2}^{(2)}, \bar{\beta}_r^{(2)}) + C_B(P_r, h_{r,0}, \bar{\lambda}_{r3}^{(2)}, \bar{\beta}_r^{(2)}) - C_{BE2}(\bar{\lambda}_{r3}^{(2)}, \bar{\lambda}_{r1}^{(2)}, \bar{\lambda}_{r2}^{(2)}, \bar{\beta}_r^{(2)}) - C_{BE}(\bar{\lambda}_{r1}^{(2)}, \bar{\lambda}_{r2}^{(2)}, \bar{\beta}_r^{(2)})) \end{array} \right. \quad (85)$$

To obtain the regions numerically, we optimize Δ_1 , Δ_2 , $\Lambda_r^{(2)}$ and $\bar{\beta}_r^{(2)}$ for the given channel mutual

informations to maximize the achievable rate regions.

- FMABC-N Protocol

$$\text{From (12)} \left\{ \begin{array}{l} R_{0,1} + R_{0,2} < \Delta_1 C(|h_{0,r}|^2 P_0) \\ R_{1,0} < \Delta_1 C(|h_{1,r}|^2 P_1) \\ R_{2,0} < \Delta_1 C(|h_{2,r}|^2 P_2) \\ R_{0,1} + R_{0,2} + R_{1,0} < \Delta_1 C(|h_{0,r}|^2 P_0 + |h_{1,r}|^2 P_1) \\ R_{0,1} + R_{0,2} + R_{2,0} < \Delta_1 C(|h_{0,r}|^2 P_0 + |h_{2,r}|^2 P_2) \\ R_{1,0} + R_{2,0} < \Delta_1 C(|h_{1,r}|^2 P_1 + |h_{2,r}|^2 P_2) \\ R_{0,1} + R_{0,2} + R_{1,0} + R_{2,0} < \Delta_1 C(|h_{0,r}|^2 P_0 + |h_{1,r}|^2 P_1 + |h_{2,r}|^2 P_2) \end{array} \right. \quad (86)$$

$$\text{From (13)} \left\{ \begin{array}{l} R_{0,1} < \Delta_2 C_B(P_r, h_{r,1}, \bar{\lambda}_{r1}^{(2)}, \bar{\beta}_r^{(2)}) \\ R_{0,2} < \Delta_2 C_B(P_r, h_{r,2}, \bar{\lambda}_{r2}^{(2)}, \bar{\beta}_r^{(2)}) \\ R_{0,1} + R_{0,2} < \Delta_2 (C_B(P_r, h_{r,1}, \bar{\lambda}_{r1}^{(2)}, \bar{\beta}_r^{(2)}) + C_B(P_r, h_{r,2}, \bar{\lambda}_{r2}^{(2)}, \bar{\beta}_r^{(2)}) - \\ \quad C_{BE}(\bar{\lambda}_{r1}^{(2)}, \bar{\lambda}_{r2}^{(2)}, \bar{\beta}_r^{(2)})) \end{array} \right. \quad (87)$$

$$\text{From (14)} \left\{ \begin{array}{l} R_{1,0} < \Delta_2 C_C(P_r, h_{r,0}, \bar{\lambda}_{r1}^{(2)}, \bar{\lambda}_{r2}^{(2)}, \bar{\beta}_r^{(2)}) \\ R_{2,0} < \Delta_2 C_C(P_r, h_{r,0}, \bar{\lambda}_{r2}^{(2)}, \bar{\lambda}_{r1}^{(2)}, \bar{\beta}_r^{(2)}) \\ R_{1,0} + R_{2,0} < \Delta_2 C(|h_{r,0}|^2 P_r) \end{array} \right. \quad (88)$$

To obtain the regions numerically, we optimize Δ_1 , Δ_2 , $\Lambda_r^{(2)}$ and $\beta_r^{(2)}$ for the given channel mutual informations to maximize the achievable rate regions.

- PMABC Protocol

$$\text{From (15)} \left\{ \begin{array}{l} R_{0,1} < \Delta_1 C(|h_{0,r}|^2 P_0) \\ R_{0,2} < \Delta_2 C(|h_{0,r}|^2 P_0) \end{array} \right. \quad (89)$$

$$\text{From (16)} \left\{ \begin{array}{l} R_{1,0} < \Delta_1 C(|h_{1,r}|^2 P_1) \\ R_{2,0} < \Delta_2 C(|h_{2,r}|^2 P_2) \end{array} \right. \quad (90)$$

$$\text{From (17)} \left\{ \begin{array}{l} R_{0,1} + R_{1,0} < \Delta_1 C(|h_{0,r}|^2 P_0 + |h_{1,r}|^2 P_1) \\ R_{0,2} + R_{2,0} < \Delta_2 C(|h_{0,r}|^2 P_0 + |h_{2,r}|^2 P_2) \end{array} \right. \quad (91)$$

$$\text{From (18)} \left\{ \begin{array}{l}

To obtain the regions numerically, we optimize Δ_1 , Δ_2 , Δ_3 and Δ_4 for the given channel mutual informations to maximize the achievable rate regions.

- PTDBC Protocol

$$\text{From (74)} \left\{ \begin{array}{l} R_{0,1} < \Delta_1 C(|h_{0,r}|^2 P_0 + |h_{0,1}|^2 P_0) + \Delta_2 C(|h_{2,r}|^2 P_2) \\ R_{0,1} < \Delta_1 C(|h_{0,1}|^2 P_0) + \Delta_3 C(|h_{r,1}|^2 P_r) \\ R_{0,2} < \Delta_1 C(|h_{0,r}|^2 P_0 + |h_{0,2}|^2 P_0) + \Delta_2 C(|h_{1,r}|^2 P_1) \\ R_{0,2} < \Delta_1 C(|h_{0,2}|^2 P_0) + \Delta_3 C(|h_{r,2}|^2 P_r) \\ R_{0,1} + R_{0,2} < \Delta_1 C(|h_{0,r}|^2 P_0 + |h_{0,1}|^2 P_0 + |h_{0,2}|^2 P_0) \\ R_{0,1} + R_{0,2} < \Delta_1 C(|h_{0,1}|^2 P_0 + |h_{0,2}|^2 P_0) + \Delta_3 C(|h_{r,1}|^2 P_r + |h_{r,2}|^2 P_r) \end{array} \right. \quad (135)$$

$$\text{From (75)} \left\{ \begin{array}{l} R_{1,0} < \Delta_2 C(|h_{1,0}|^2 P_1) + \Delta_3 C(|h_{r,0}|^2 P_r + |h_{r,2}|^2 P_r) \\ R_{1,0} < \Delta_2 C(|h_{1,0}|^2 P_1 + |h_{1,r}|^2 P_1) \\ R_{2,0} < \Delta_2 C(|h_{2,0}|^2 P_2) + \Delta_3 C(|h_{r,0}|^2 P_r + |h_{r,1}|^2 P_r) \\ R_{2,0} < \Delta_2 C(|h_{2,0}|^2 P_2 + |h_{2,r}|^2 P_2) \\ R_{1,0} + R_{2,0} < \Delta_2 C(|h_{1,0}|^2 P_1 + |h_{2,0}|^2 P_2) + \Delta_3 C(|h_{r,0}|^2 P_r) \\ R_{1,0} + R_{2,0} < \Delta_2 C(|h_{1,0}|^2 P_1 + |h_{1,r}|^2 P_1 + |h_{2,0}|^2 P_2 + |h_{2,r}|^2 P_2) \end{array} \right. \quad (136)$$

To obtain the regions numerically, we optimize Δ_1 , Δ_2 , and Δ_3 for the given channel mutual informations to maximize the achievable rate regions.

VII. NUMERICAL ANALYSIS

In this section, we numerically evaluate the rate regions obtained in the previous section for the case of two terminal nodes $m = 2$. We first compare the achievable rate regions and outer bounds of the different protocols, using different combinations of encoding schemes, for both reciprocal channel H_1 and asymmetric channel H_2 :

$$\mathbf{H}_1 = \begin{bmatrix} 0 & 0.3 & 0.05 & 1 \\ 0.3 & 0 & 1.5 & 1 \\ 0.05 & 1.5 & 0 & 0.2 \\ 1 & 1 & 0.2 & 0 \end{bmatrix} \quad \mathbf{H}_2 = \begin{bmatrix} 0 & 0.9 & 0.4 & 1 \\ 0 & 0 & 0.02 & 1 \\ 0 & 0.02 & 0 & 0.5 \\ 1 & 1 & 0.5 & 0 \end{bmatrix}. \quad (137)$$

We then proceed to examine the maximal sum-rate $R_{0,1} + R_{0,2} + R_{1,0} + R_{2,0}$. Finally, we dedicate the last section to the evaluation of the cooperation coding gain.

A. Achievable rate region comparisons

We compare the achievable rate regions of the different protocols, using different combinations of encoding schemes, with the simplest protocol. We set $P_0 = P_1 = P_2 = P_r = 0$ dB and $H = H_1$. In Fig. 6, there are three achievable rate regions; 1) the simplest protocol (Simple), 2) convex hull of the FMABC, PMABC, FTDBC, and PTDBC protocols (MB) and 3) convex hull of the FMABC-N, PMABC-NR, FTDBC-NR, and PTDBC-NR protocols (MB-NR). The 4-dimensional rate regions $(R_{0,1}, R_{0,2}, R_{1,0}, R_{2,0})$ are projected onto $(R_{0,1} + R_{0,2}, R_{1,0} + R_{2,0})$ 2-dimensional space. For more realistic comparison, we add lower limits of individual data rates, i.e., $R_{0,1} \geq 0.01, R_{0,2} \geq 0.01, R_{1,0} \geq 0.01, R_{2,0} \geq 0.01$ to guarantee minimum information flow in each data link. Without this limitation, the maximum sum-rates will be reached when both the transmission rates $R_{0,2}$ and $R_{2,0}$ equal zero at least in the Simplest case because the link between the relay and the node 2 is very poor. We want to emphasize that the value of the minimum data rate (set as 0.01 here) do not affect the following simulation outcomes. The Simple region is outer bounded by the MB region. This implies that the proposed protocols using only conventional MAC and extended Marton's broadcasting coding largely enhance the performance. Furthermore, we can significantly improve the achievable rate region by Network coding and Random binning schemes (in MB-NR).

We next evaluate the achievable rate regions and outer bounds for different SNR regimes and channel conditions. We plot the inner bounds of the FMABC-N, PMABC-NR, FTDBC-NR, and PTDBC-NR protocols. The main outcome is that different protocols are optimal under different channel conditions.

Fig. 6. Comparison of protocol and coding gains with $P_0 = P_1 = P_2 = P_r = 0$ dB, $H = H_1$ and rate constraints ($R_{0,1} \geq 0.01$, $R_{0,2} \geq 0.01$, $R_{1,0} \geq 0.01$, $R_{2,0} \geq 0.01$).

This is because the amount of side information and multiple access interference is different. In the low SNR regime (Fig. 7), the FMABC-N protocol outperforms the other protocols since the amount of both side information and multiple access interference is relatively small. However, in the high SNR regime (Fig. 10), the FTDBC-NR protocol becomes the best since it exploits side information more effectively.

In Fig. 8 and 9, the PMABC-NR protocol outperforms the other three protocols. The first case (Fig. 8) is when channel is asymmetric as $0 \rightarrow 1$ and $0 \rightarrow 2$ are very good but the opposite direct links are almost disconnected. In this case, using side information in nodes 1 and 2 and multiple access for node 0 would be the best choice since the quality of direct links are different. The second is when we have different power allocation. Indeed, if we allow larger input power for the base station (node 0) and relay (node r), the direct links from the base station are good enough to convey information. The terminal nodes can then exploit the side information efficiently. Therefore, the PMABC-NR protocol has the best performance in this channel condition.

There is no significant different between two TDBC protocols, the FTDBC-NR and PTDBC-NR protocols. Since only difference is using multiple access or sequential transmitting for terminal nodes ($\in \mathcal{B}$), two type of side information, i.e., one is from node 0 to node i , the other is the opposite direction are both available. The small gap is from the efficiency of multiple access and generated interference.

Fig. 7. Comparison with $P_0 = P_1 = P_2 = P_r = 0$ dB, $H = H_1$.

Fig. 8. Comparison with $P_0 = P_1 = P_2 = P_r = 0$ dB, $H = H_2$.

Fig. 9. Comparison with $P_0 = P_r = 20$, $P_1 = P_2 = 0$ dB, $H = H_1$.

Fig. 10. Comparison with $P_0 = P_1 = P_2 = P_r = 20$ dB, $H = H_1$.

B. Sum rate comparison

In Fig. 11, we plot the maximum sum rates ($R_{0,1} + R_{0,2} + R_{1,0} + R_{2,0}$) of FMABC-N, PMABC-NR, FTDBC-NR and PTDBC-NR protocols and the corresponding outer bounds. As expected, in the low SNR regime (≤ 15 dB) two MABC protocols are better than the two FTDBC protocols, while the FTDBC protocols are better in the high SNR regime (≥ 15 dB). We also note that the slope for MABC protocols changes at around ≤ 15 dB. Indeed, the multiple access interference increases with SNR and limit the maximum sum rate of the MABC protocols. However, the slopes are the same in the outer bounds since the sum rate constraints don't affect to the outer bounds.

Fig. 11. Sum rate comparison with $H = H_1$.

C. Cooperation coding gain

To show the cooperation coding gain, we plot the achievable rate region of the different protocols with and without cooperation. In Fig. 12, we fixed the data rates $(R_{0,1}, R_{2,0})$ to the rate pair $((0.19, 0.01))$ and plot rate regions in the $(R_{1,0}, R_{0,2})$ domain. We do this to highlight the cooperation gain, which comes from re-allocating node 1's transmission resources (i.e. relative power) to the two information flows; $1 \rightarrow r$ ($R_{1,0}$) and $1 \rightarrow 2$ ($R_{0,2}$). As expected -NRC protocols achieve much better performance than -NR protocols. Notably, the cooperation protocols improve $R_{0,2}$ without any degradation of $R_{1,0}$ in the FTDBC protocol. In contrast, the maximum $R_{1,0}$ of the PMABC-NRC protocol is less than that of its PMABC-NR only protocol. We explain this by the fact that in our achievable rate region, we used a simplified and sub-optimal (successive decoding like) receiver in the PMABC-NRC protocol instead of using a fully general joint-decoder (as is done in the simpler PMABC-NR protocol), which limits the $R_{1,0}$. If we were to enhance the PMABC-NRC scheme by using the general joint decoder, the maximum $R_{1,0}$ would be reached and the overall performance would improve - a technically challenging task left for future work. We furthermore expect the gains of cooperation to increase if many more terminal nodes are able to exploit node 1's cooperative broadcasting; however these situations with current regions are too complex to be evaluated numerically.

VIII. CONCLUSION

In this paper, we introduced four new temporal protocols which fully exploit the two-way nature of the data and outperform simple routing or multi-hop communication schemes: the FMABC, PMABC,

Fig. 12. Comparison with $P_0 = P_1 = P_2 = P_r = 0$ dB, $H = H_1$ and $R_{0,1} = 0.19$, $R_{2,0} = 0.01$.

FTDBC, and PTDBC protocols. We also proposed various coding schemes: Network coding, Random binning and user cooperations which exploit over-heard and own-message side information. We derived achievable rate regions as well as outer bounds for the proposed protocols, using different combinations of encoding schemes, for a decode and forward relay. We compared these regions in the Gaussian noise channel. With numerical evaluations, we verified that different protocols achieve the best performance in different channel conditions and we highlighted the relative gains achieved by network coding, random binning and compress-and-forward-type cooperation between terminal nodes.

APPENDIX A

LEMMA FOR THEOREM 1

Lemma 21: For a given subset $S \subseteq \mathcal{B}$, $|S| > 1$, we define $\mathbf{w} = \{w_i, i \in S\}$, $\mathbf{w}_0 = \{w_{i0} | i \in S\}$, $\mathbf{u}(\mathbf{w}_0) = \{\mathbf{u}_i(w_{i0}) | i \in S\}$, $\mathbf{U} = \{U_i | i \in S\}$ and the set

$$D_{\mathbf{w}} := \left\{ \mathbf{u}(\mathbf{w}_0) \in A(\mathbf{U}) | \mathbf{w}_0 \in \bigotimes_{i \in S} B_{w_i}^i \right\}. \quad (138)$$

Then for any choice of $\mathbf{w}$, $\epsilon > 0$ and sufficiently large n :

$$P[\|D_{\mathbf{w}}\| = 0] \leq \epsilon \quad (139)$$

with

$$\sum_{i \in S} R_i < \sum_{i \in S} (I(U_i; Y_i) - I(U_i; U_{S(i)})) - |S|\epsilon - \delta(\epsilon) \quad (140)$$

where $\delta(\epsilon) \rightarrow 0$ as $\epsilon \rightarrow 0$. □

Proof: We use the similar proofs to Lemma in [9]. From Chebychev's inequality, we have

$$P[\|D_{\mathbf{w}}\| = 0] \leq P[\|D_{\mathbf{w}}\| - E[\|D_{\mathbf{w}}\|] > \epsilon E[\|D_{\mathbf{w}}\|]] \leq \frac{(\sigma[\|D_{\mathbf{w}}\|])^2}{\epsilon^2 (E[\|D_{\mathbf{w}}\|])^2} \quad (141)$$

and

$$P[\mathbf{u}(\mathbf{w}_0) \in D_{\mathbf{w}}] \geq 2^{n(H(\mathbf{U}) - \sum_{i \in S} H(U_i) - \delta(\epsilon))} \quad (142)$$

$$= 2^{-n(\sum_{i \in S} I(U_i; U_{S(i)}) + \delta(\epsilon))} \quad (143)$$

Therefore,

$$E[\|D_{\mathbf{w}}\|] = \prod_{i \in S} \|B_{w_i}^i\| \cdot P[\mathbf{u}(\mathbf{w}_0) \in D_{\mathbf{w}}] \quad (144)$$

$$\geq 2^{n(\sum_{i \in S} (I(U_i; Y_i) - R_i - \epsilon) - \sum_{j \in S} I(U_j; U_{S(j)}) - \delta(\epsilon))} \quad (145)$$

To find an upper bound of $(\sigma[\|D_{\mathbf{w}}\|])^2$, we first estimate $E[\|D_{\mathbf{w}}\|^2]$.

$$\begin{aligned} E[\|D_{\mathbf{w}}\|^2] &= \sum_{\mathbf{u}(\mathbf{w}_0) \in D_{\mathbf{w}}} P[\mathbf{u}(\mathbf{w}_0) \in D_{\mathbf{w}}] + \\ &\quad \sum_{\substack{\mathbf{u}(\mathbf{w}_0), \mathbf{u}(\mathbf{w}_1) \in D_{\mathbf{w}} \\ \mathbf{u}(\mathbf{w}_0) \neq \mathbf{u}(\mathbf{w}_1)}} P[\mathbf{u}(\mathbf{w}_0) \in D_{\mathbf{w}}] \cdot P[\mathbf{u}(\mathbf{w}_1) \in D_{\mathbf{w}}] \end{aligned} \quad (146)$$

$$\begin{aligned} &\leq \prod_{i \in S} \|B_{w_i}^i\| \cdot 2^{-n(\sum_{j \in S} I(U_j; U_{S(j)}) - \delta(\epsilon))} + \\ &\quad \left(\prod_{i \in S} \|B_{w_i}^i\|^2 - \prod_{i \in S} \|B_{w_i}^i\| \right) \cdot 2^{-2n(\sum_{j \in S} I(U_j; U_{S(j)}) - \delta(\epsilon))} \end{aligned} \quad (147)$$

Thus, from (145) and (147) we have

$$(\sigma[\|D_{\mathbf{w}}\|])^2 = E[\|D_{\mathbf{w}}\|^2] - E[\|D_{\mathbf{w}}\|]^2 \quad (148)$$

$$\leq \prod_{i \in S} \|B_{w_i}^i\| \cdot 2^{-n(\sum_{j \in S} I(U_j; U_{S(j)}) - \delta(\epsilon))} \quad (149)$$

$$\leq 2^{n(\sum_{i \in S} (I(U_i; Y_i) - R_i - \epsilon) - \sum_{j \in S} I(U_j; U_{S(j)}) + \delta(\epsilon))} \quad (150)$$

From (145) and (150) for sufficiently large n

$$P[\|D_{\mathbf{w}}\| = 0] \leq \epsilon \quad (151)$$

with

$$\sum_{i \in S} R_i < \sum_{i \in S} (I(U_i; Y_i) - I(U_i; U_{S(i)})) - |S|\epsilon - \delta(\epsilon) \quad (152)$$

■

APPENDIX B

PROOF OF THEOREM 4

Proof: Random code generation: For simplicity of exposition we take $|\mathcal{Q}| = 1$.

1) Phase 1 variables: Generate random $(n \cdot \Delta_{1,n})$ -length sequences

- $\mathbf{x}_0^{(1)}(w_{\{0\},\mathcal{B}})$ i.i.d. with $p^{(1)}(x_0)$, $w_{\{0\},\mathcal{B}} \in \mathcal{S}_{\{0\},\mathcal{B}}$
- $\mathbf{x}_i^{(1)}(w_{i,0})$ i.i.d. with $p^{(1)}(x_i)$, $w_{i,0} \in \mathcal{S}_{i,0}$, $\forall i \in \mathcal{B}$

2) Phase 2 variables: Generate random $(n \cdot \Delta_{2,n})$ -length sequences

- $\mathbf{u}_i^{(2)}(w_{r_i})$ with $p^{(2)}(\mathbf{u}_i)$, $w_{r_i} \in \{0, 1, \dots, \lfloor 2^{nR_{r_i}} \rfloor - 1\} := \mathcal{S}_{r_i}$, where

$$p^{(2)}(\mathbf{u}_i) = \begin{cases} \frac{1}{\|A^{(2)}(U_i)\|}, & \mathbf{u}_i \in A^{(2)}(U_i) \\ 0, & \text{otherwise.} \end{cases} \quad (153)$$

and $R_{r_i} = \max\{R_{0,i}, R_{i,0}\} + (\Delta_2 I(U_i^{(2)}; Y_i^{(2)}) - 4\epsilon - R_{0,i})$ for $i \in [1, m]$.

and define bin $B_j^i := \{w_{r_i} | w_{r_i} \in [j \cdot \lfloor 2^{n(\Delta_2 I(U_i^{(2)}; Y_i^{(2)}) - R_{0,i} - 4\epsilon)} \rfloor, (j+1) \cdot \lfloor 2^{n(\Delta_2 I(U_i^{(2)}; Y_i^{(2)}) - R_{0,i} - 4\epsilon)} \rfloor - 1]\}$ for $j \in \{0, 1, \dots, \lfloor 2^{n \max\{R_{0,i}, R_{i,0}\}} \rfloor - 1\}$.

Encoding: During phase 1, encoders of terminal nodes send the codewords $\mathbf{x}_0^{(1)}(w_{\{0\},\mathcal{B}})$, $\mathbf{x}_i^{(1)}(w_{i,0})$. Relay r estimates $\hat{w}_{0,i}$ and $\hat{w}_{i,0}$ after phase 1 using jointly typical decoding, then constructs $w_i = \hat{w}_{0,i} \oplus \hat{w}_{i,0}$. To transmit messages $(w_1, \dots, w_m)$, pick $(w_{r_1}, \dots, w_{r_m}) \in \bigotimes_{i=1}^m B_{w_i}^i$ such that $\mathbf{u}_T^{(2)}(w_{r_T}) \in A^{(2)}(U_T)$, $\forall T \subseteq \mathcal{B}$, $|T| > 1$, where $w_{r_T} := \{w_{r_i} | i \in T\}$. Such a $(w_{r_1}, \dots, w_{r_m})$ exists with high probability if

$$\sum_{i \in T} R_{0,i} < \sum_{i \in T} \left(\Delta_2 I(U_i^{(2)}; Y_i^{(2)}) - \Delta_2 I(U_i^{(2)}; U_{T(i)}^{(2)}) \right) - |T|\epsilon - \delta(\epsilon) \quad \forall T \subseteq \mathcal{B}, |T| > 1 \quad (154)$$

from Lemma 21. Then the relay finds a $\mathbf{x}_r^{(2)}$ jointly typical with $(\mathbf{u}_1^{(2)}(w_{r_1}), \dots, \mathbf{u}_m^{(2)}(w_{r_m}))$ and assigns it as the codeword corresponding to $(w_1, \dots, w_m)$. Relay r sends $\mathbf{x}_r^{(2)}(w_1, \dots, w_m)$ during phase 2.

Decoding: Node 0 estimates $\tilde{w}_{i,0}$ after phase 2 using jointly typical decoding. Since $w_i = w_{0,i} \oplus w_{i,0}$ and 0 knows $w_{0,i}$, node 0 can reduce the number of possible w_{r_i} and likewise at node i , the cardinality of w_{r_i} is $2^{n(\Delta_2 I(U_i^{(2)}; Y_i^{(2)}) - 4\epsilon)}$.

Error analysis: Recall that $w_{r_T} = \{w_{r_i} | i \in T\}$. Then,

$$P[E] = P[E_{enc} \cup E_{dec}] \leq P[E_{enc}] + P[E_{dec}] \quad (155)$$

$$\leq \epsilon + \sum_{i=1}^m P[E_{\{0\},\{i\}}] + P[E_{\{i\},\{0\}}] \quad (156)$$

where E is the entire decoding error event, E_{enc} is the set of encoding error events, and E_{dec} is the set of decoding error events. $P[E_{enc}]$ may be driven to 0 as $n \rightarrow \infty$ by (154) and E_{dec} may be decomposed into individual decoding error events on each link as:

$$P[E_{\{0\},\{i\}}] \leq P[E_{\mathcal{M},\{r\}}^{(1)} \cup E_{\{r\},\{i\}}^{(2)}] \quad (157)$$

$$\leq P[E_{\mathcal{M},\{r\}}^{(1)}] + P[E_{\{r\},\{i\}}^{(2)} | \bar{E}_{\mathcal{M},\{r\}}^{(1)}] \quad (158)$$

$$P[E_{\{i\},\{0\}}] \leq P[E_{\mathcal{M},\{r\}}^{(1)} \cup E_{\{r\},\{0\}}^{(2)}] \quad (159)$$

$$\leq P[E_{\mathcal{M},\{r\}}^{(1)}] + P[E_{\{r\},\{0\}}^{(2)} | \bar{E}_{\mathcal{M},\{r\}}^{(1)}] \quad (160)$$

$P[E_{\mathcal{M},\{r\}}^{(1)}]$ tends to zero as $n \rightarrow \infty$ by Theorem 15.3.6 in [6] and the condition in (12).

$$P[E_{\{r\},\{i\}}^{(2)} | \bar{E}_{\mathcal{M},\{r\}}^{(1)}] \leq P[\bar{D}^{(2)}(\mathbf{u}_i(w_{r_i}), \mathbf{y}_i)] + P[\cup_{\tilde{w}_{r_i} \in \cup B_{\tilde{w}_{0,i}}^i \oplus w_{i,0}} D^{(2)}(\mathbf{u}_i(\tilde{w}_{r_i}), \mathbf{y}_i)] \quad (161)$$

$$\leq 2\epsilon \quad (162)$$

$$P[E_{\{r\},\{0\}}^{(2)} | \bar{E}_{\mathcal{M},\{r\}}^{(1)}] \leq P[\bar{D}^{(2)}(\mathbf{u}_B(w_{r_B}), \mathbf{y}_0)] + \sum_{T \subseteq \mathcal{B}} P[\cup_{\tilde{w}_{T,\{0\}} \neq w_{T,\{0\}}} D^{(2)}(\mathbf{u}_T(\tilde{w}_{r_T}), \mathbf{u}_{\bar{T}}(w_{r_{\bar{T}}}), \mathbf{y}_0)] \quad (163)$$

$$\leq \epsilon + \sum_{T \subseteq \mathcal{B}} 2^{nR_{T,\{0\}}} 2^{-n \cdot \Delta_{2,n}(I(U_T^{(2)}; Y_0^{(2)}, U_{\bar{T}}^{(2)}) - \epsilon')} \quad (164)$$

The total cardinality of the case $(\tilde{w}_{r_T} \neq w_{r_T})$ is bounded by $2^{nR_{T,\{0\}}}$ since $\tilde{w}_{r_T}$ is uniquely specified by $\tilde{w}_{T,\{0\}}$ if $w_{\bar{T},\{0\}}$ is given.

Since $\epsilon > 0$ is arbitrary, the conditions of Theorem 4 and the AEP property ensure that the right hand sides of (162) and (164) tend to 0 as $n \rightarrow \infty$. By Fenchel-Bunt's theorem in [12], it is sufficient to restrict $|\mathcal{Q}| \leq 2^{m+1} - 1$ since we have $2^{m+1} - 1$ in (12). ■

APPENDIX C

PROOF OF THEOREM 6

Proof: Random code generation: For simplicity of exposition only, we take $|\mathcal{Q}| = 1$. For all $i \in [1, m]$, first we generate a partition of $\mathcal{S}_{0,i}$ randomly by independently assigning every index $w_{0,i} \in \mathcal{S}_{0,i}$ to a set $\mathcal{S}_{0,i}(k)$, with a uniform distribution over the indices $k \in \{0, \dots, \lfloor 2^{nR_{0,i:1}} \rfloor - 1\} := \mathcal{S}_{0,i:1}$. We denote by $s_{0,i}(w_{0,i})$ the index k of $\mathcal{S}_{0,i}(k)$ to which $w_{0,i}$ belongs.

- 1) Phase $j \in [1, m]$: Generate random $(n \cdot \Delta_{j,n})$ -length sequences

- $\mathbf{v}_{0i}^{(j)}(w_{0,i:2})$ with $p^{(j)}(\mathbf{v}_{0i})$, $w_{0,i:2} \in \{0, 1, \dots, \lfloor 2^{nR_{0,i:2}} \rfloor - 1\} := \mathcal{S}_{0,i:2}$, where

$$p^{(j)}(\mathbf{v}_{0i}) = \begin{cases} \frac{1}{\|A^{(j)}(V_{0i})\|}, & \mathbf{v}_{0i} \in A^{(j)}(V_{0i}) \\ 0, & \text{otherwise.} \end{cases} \quad (165)$$

and $R_{0,i:2} = R_{0,i:1} + \sum_{j=1}^m \Delta_j I(V_{0i}^{(j)}; Y_i^{(j)}) - \epsilon'$. Then we define bin $B_k^i := \{w_{0,i:2} | w_{0,i:2} \in [k \cdot \lfloor 2^{n(\sum_{j=1}^m \Delta_j I(V_{0i}^{(j)}; Y_i^{(j)}) + R_{0,i:1} - R_{0,i} - \epsilon') \rfloor}, (k+1) \cdot \lfloor 2^{n(\sum_{j=1}^m \Delta_j I(V_{0i}^{(j)}; Y_i^{(j)}) + R_{0,i:1} - R_{0,i} - \epsilon') \rfloor} - 1]\}$ for $k \in \{0, 1, \dots, \lfloor 2^{nR_{0,i}} \rfloor - 1\}$.

- $\mathbf{x}_j^{(j)}(w_{j,0})$ i.i.d. with $p^{(j)}(x_j)$, $w_{j,0} \in \mathcal{S}_{j,0}$

2) Phase $m+1$: Generate random $(n \cdot \Delta_{m+1,n})$ -length sequences

- $\mathbf{u}_i^{(m+1)}(w_{r_i})$ with $p^{(m+1)}(\mathbf{u}_i)$, $w_{r_i} \in \{0, 1, \dots, \lfloor 2^{nR_{r_i}} \rfloor - 1\} := \mathcal{S}_{r_i}$, where

$$p^{(m+1)}(\mathbf{u}_i) = \begin{cases} \frac{1}{\|A^{(m+1)}(U_i)\|}, & \mathbf{u}_i \in A^{(m+1)}(U_i) \\ 0, & \text{otherwise.} \end{cases} \quad (166)$$

and $R_{r_i} = \max\{R_{0,i:1}, R_{i,0}\} + (\Delta_{m+1} I(U_i^{(m+1)}; Y_i^{(m+1)}) - 4\epsilon - R_{0,i:1})$.

and define bin $C_k^i := \{w_{r_i} | w_{r_i} \in [k \cdot \lfloor 2^{n(\Delta_{m+1} I(U_i^{(m+1)}; Y_i^{(m+1)}) - R_{0,i:1} - 4\epsilon) \rfloor}, (k+1) \cdot \lfloor 2^{n(\Delta_{m+1} I(U_i^{(m+1)}; Y_i^{(m+1)}) - R_{0,i:1} - 4\epsilon) \rfloor} - 1]\}$ for $k \in \{0, 1, \dots, \lfloor 2^{n \max\{R_{0,i:1}, R_{i,0}\}} \rfloor - 1\}$.

Encoding:

- 1) To transmit $(w_{0,1}, \dots, w_{0,m})$, node 0 picks $(w_{0,1:2}, \dots, w_{0,m:2}) \in \bigotimes_{i=1}^m B_{w_{0,i}}^i$ such that $\mathbf{v}_{0S}^{(j)}(w_{\{0\},S:2}) \in A^{(j)}(V_{0S})$, $\forall j \in [1, m], \forall S \subseteq \mathcal{B}$, $|S| > 1$. Such a $(w_{0,1:2}, \dots, w_{0,m:2})$ exists with high probability if

$$\sum_{i \in S} (R_{0,i} - R_{0,i:1}) < \sum_{i \in S} \sum_{j=1}^m \Delta_j I(V_{0i}^{(j)}; Y_i^{(j)}) - \Delta_j I(V_{0i}^{(j)}; V_{0S(i)}^{(j)}) - \delta(\epsilon) \quad (167)$$

for $S \subseteq \mathcal{B}$, $|S| > 1$ from Lemma 21. Then node 0 finds a $\mathbf{x}_0^{(i)}$ jointly typical with

$(\mathbf{v}_{01}^{(i)}(w_{0,1:2}), \dots, \mathbf{v}_{0m}^{(i)}(w_{0,m:2}))$ and designate it as the codeword corresponding to $(w_{0,1}, \dots, w_{0,m})$ for all $i \in [1, m]$. Node 0 sends $\mathbf{x}_0^{(i)}(w_{0,1}, \dots, w_{0,m})$ during phase i .

- 2) During phase i , encoder of terminal node i sends the codeword $\mathbf{x}_i^{(i)}(w_{i,0})$ for $i \in [1, m]$.
- 3) Relay r estimates $\hat{w}_{0,i}$ and $\hat{w}_{i,0}$ after phase m using jointly typical decoding, then constructs $w_i = \hat{w}_{0,i:1} \oplus \hat{w}_{i,0}$. To transmit a pair of messages $(w_1, \dots, w_m)$, pick a pair $(w_{r_1}, \dots, w_{r_m}) \in \bigotimes_{i=1}^m C_{w_i}^i$ such that $\mathbf{u}_S^{(m+1)}(w_{r_S}) \in A^{(m+1)}(U_S)$. Such a $(w_{r_1}, \dots, w_{r_m})$ exists with high probability if

$$\sum_{i \in S} R_{0,i:1} < \sum_{i \in S} \Delta_{m+1} I(U_i^{(m+1)}; Y_i^{(m+1)}) - \Delta_{m+1} I(U_i^{(m+1)}; U_{S(i)}^{(m+1)}) - |S|\epsilon - \delta(\epsilon) \quad (168)$$

for $S \subseteq \mathcal{B}$, $|S| > 1$ from Lemma 21. Then the relay finds a $\mathbf{x}_r^{(m+1)}$ jointly typical with $(\mathbf{u}_1^{(m+1)}(w_{r_1}), \dots, \mathbf{u}_m^{(m+1)}(w_{r_m}))$ and designate it as the codeword corresponding to $(w_1, \dots, w_m)$. Relay r sends $\mathbf{x}_r^{(m+1)}(w_1, \dots, w_m)$ during phase $m + 1$.

Decoding: For all $i \in [1, m]$,

- 1) Node 0 estimates $\tilde{w}_{i,0}$ after phase $m + 1$ using jointly typical decoding. Since $w_i = w_{0,i:1} \oplus w_{i,0}$ and 0 knows $w_{0,i}$, node 0 can reduce the number of possible w_i .
- 2) Node i estimates $\tilde{w}_{r_i}$ after phase $m + 1$ using jointly typical decoding. Similar to the case of node 0, node i can reduce the cardinality of w_{r_i} to $2^{n(\Delta_{m+1}I(U_i^{(m+1)}; Y_i^{(m+1)}) - 4\epsilon)}$ and node i decodes $\tilde{w}_{0,i:1}$ from the bin index of $\tilde{w}_{r_i}$. Then, node i estimates $\tilde{w}_{0,i:2}$ using jointly typical decoding of the sequence $(\mathbf{v}_{0i}^{(j)}(\tilde{w}_{0,i:2}), \mathbf{y}_i^{(j)})$, for all $j \neq i$. Since node i knows the bin index $s_{\tilde{w}_{0,i}}(\tilde{w}_{0,i})$ as $\tilde{w}_{0,i:1}$, it can reduce the cardinality of $w_{0,i:2}$ to $2^{n(\sum_{j \neq i} \Delta_j I(V_{0i}^{(j)}; Y_i^{(j)}) - \epsilon')}$. After decoding $\tilde{w}_{0,i:2}$, node i finally decodes $\tilde{w}_{0,i}$ from the bin index of $\tilde{w}_{0,i:2}$.

Error analysis:

$$P[E] = P[E_{enc} \cup E_{dec}] \leq P[E_{enc}] + P[E_{dec}] \quad (169)$$

$$\leq \epsilon + \sum_{i=1}^m P[E_{\{0\},\{i\}}] + P[E_{\{i\},\{0\}}] \quad (170)$$

where E is the entire error event, E_{enc} is the set of encoding error events, and E_{dec} is the set of decoding error events. $P[E_{enc}]$ is upper bounded by sufficiently small number ϵ from (167) and (168). E_{dec} can be separated by individual decoding error events in each link. Then $\forall i \in [1, m]$,

$$P[E_{\{0\},\{i\}}] \leq P[(\cup_{j=1}^m E_{\{0,j\},\{r\}}^{(j)}) \cup E_{\{r\},\{i\}}^{(m+1)} \cup E_{\{0\},\{i\}}^{(m+1)}] \quad (171)$$

$$\leq P[\cup_{j=1}^m E_{\{0,j\},\{r\}}^{(j)}] + P[E_{\{r\},\{i\}}^{(m+1)} | \cap_{j=1}^m \bar{E}_{\{0,j\},\{r\}}^{(j)}] + P[E_{\{0\},\{i\}}^{(m+1)} | (\cap_{j=1}^m \bar{E}_{\{0,j\},\{r\}}^{(j)}) \cap \bar{E}_{\{r\},\{i\}}^{(m+1)}] \quad (172)$$

$$P[E_{\{i\},\{0\}}] \leq P[(\cup_{j=1}^m E_{\{0,j\},\{r\}}^{(j)}) \cup E_{\{r\},\{0\}}^{(m+1)}] \quad (173)$$

$$\leq P[\cup_{j=1}^m E_{\{0,j\},\{r\}}^{(j)}] + P[E_{\{r\},\{0\}}^{(m+1)} | \cap_{j=1}^m \bar{E}_{\{0,j\},\{r\}}^{(j)}] \quad (174)$$

Now we will show that $P[\cup_{j=1}^m E_{\{0,j\},\{r\}}^{(j)}]$, $P[E_{\{r\},\{i\}}^{(m+1)} | \cap_{j=1}^m \bar{E}_{\{0,j\},\{r\}}^{(j)}]$, $P[E_{\{0\},\{i\}}^{(m+1)} | (\cap_{j=1}^m \bar{E}_{\{0,j\},\{r\}}^{(j)}) \cap \bar{E}_{\{r\},\{i\}}^{(m+1)}]$ and $P[E_{\{r\},\{0\}}^{(m+1)} | \cap_{j=1}^m \bar{E}_{\{0,j\},\{r\}}^{(j)}]$ tend to zero as $n \rightarrow \infty$. For the convenience of analysis we

define $B_R^i(w_{0,i:1}) = \cup_{w_{0,i} \in S_{0,i}(w_{0,i:1})} B_{w_{0,i}}^i$ and $C_R^i(w_{i,0}) = \cup_{w_{0,i:1} \in S_{0,i:1} C_{w_{0,i:1} \oplus w_{i,0}}^i$. Then,

$$P[\cup_{j=1}^m E_{\{0,j\},\{r\}}^{(j)}] \leq \sum_{j=1}^m P[\bar{D}^{(j)}(\mathbf{v}_{0B}(w_{\{0\},B:2}), \mathbf{x}_j(w_{j,0}), \mathbf{y}_r)] + P \left[\bigcup_{\tilde{w}_{\mathcal{M},\mathcal{M}} \neq w_{\mathcal{M},\mathcal{M}}} \left(\bigcap_{j=1}^m D^{(j)}(\mathbf{v}_{0B}(\tilde{w}_{\{0\},B:2}), \mathbf{x}_j(\tilde{w}_{j,0}), \mathbf{y}_r) \right) \right] \quad (175)$$

$$\leq m \cdot \epsilon + \sum_{T,S \in \mathcal{B}} \sum_{\tilde{w}_{\{0\},T}} \sum_{\tilde{w}_{S,\{0\}}} \left[\prod_{s \in S} P[D^{(s)}(\mathbf{v}_{0T}(\tilde{w}_{\{0\},T:2}), \mathbf{v}_{0\bar{T}}(w_{\{0\},\bar{T}:2}), \mathbf{x}_s(\tilde{w}_{s,0}), \mathbf{y}_r)] \cdot \prod_{s \in \bar{S}} P[D^{(s)}(\mathbf{v}_{0T}(\tilde{w}_{\{0\},T:2}), \mathbf{v}_{0\bar{T}}(w_{\{0\},\bar{T}:2}), \mathbf{x}_s(w_{s,0}), \mathbf{y}_r)] \right] \quad (176)$$

$$\leq m\epsilon + \sum_{T,S \in \mathcal{B}} 2^{n(R_{\{0\},T} + R_{S,\{0\}})} \cdot 2^{-n(\sum_{s \in S} \Delta_{s,n} I(V_{0T}^{(s)}; X_s^{(s)}; Y_r^{(s)}, V_{0\bar{T}}^{(s)}) + \sum_{s \in \bar{S}} \Delta_{s,n} I(V_{0T}^{(s)}; Y_r^{(s)}, V_{0\bar{T}}^{(s)} | X_s^{(s)}) - \epsilon'')} \quad (177)$$

The total cardinality of the case $(\tilde{w}_{\{0\},T:2} \neq w_{\{0\},T:2})$ is bounded by $2^{nR_{\{0\},T}}$ since $\tilde{w}_{\{0\},T:2}$ is uniquely specified with $\tilde{w}_{\{0\},T}$ if $w_{\{0\},\bar{T}:2}$ is given. Also,

$$P[E_{\{r\},\{i\}}^{(m+1)} | \cap_{j=1}^m \bar{E}_{\{0,j\},\{r\}}^{(j)}] \leq P[\bar{D}^{(m+1)}(\mathbf{u}_i(w_{r_i}), \mathbf{y}_i)] + P[\cup_{\tilde{w}_{r_i} \in C_R^i(w_{i,0})} D^{(m+1)}(\mathbf{u}_i(\tilde{w}_{r_i}), \mathbf{y}_i)] \quad (178)$$

$$\leq \epsilon + |C_R^i(w_{i,0})| \cdot 2^{-n(\Delta_{m+1,n} I(U_i^{(m+1)}; Y_i^{(m+1)}) - 3\epsilon)} \quad (179)$$

$$P[E_{\{0\},\{i\}}^{(m+1)} | (\cap_{j=1}^m \bar{E}_{\{0,j\},\{r\}}^{(j)}) \cap \bar{E}_{\{r\},\{i\}}^{(m+1)}] \leq \sum_{j \neq i} P[\bar{D}^{(j)}(\mathbf{v}_{0i}(w_{0,i:2}), \mathbf{y}_i)] + P \left[\cup_{\tilde{w}_{0,i:2} \in B_R^i(w_{0,i:1})} \left(\cap_{j \neq i} D^{(j)}(\mathbf{v}_{0i}(\tilde{w}_{0,i:2}), \mathbf{y}_i) \right) \right] \quad (180)$$

$$\leq (m-1)\epsilon + |B_R^i(w_{0,i:1})| \cdot 2^{-n(\sum_{j \neq i} \Delta_{j,n} I(V_{0i}^{(j)}; Y_i^{(j)}) - \epsilon'')} \quad (181)$$

$$P[E_{\{r\},\{0\}}^{(m+1)} | \cap_{j=1}^m \bar{E}_{\{0,j\},\{r\}}^{(j)}] \leq P[\bar{D}^{(m+1)}(\mathbf{u}_B(w_{r_B}), \mathbf{y}_0)] + \sum_{S \subseteq \mathcal{B}} P[\cup_{\tilde{w}_{S,\{0\}} \neq w_{S,\{0\}}} D^{(m+1)}(\mathbf{u}_S(\tilde{w}_{r_S}), \mathbf{u}_{\bar{S}}(w_{r_{\bar{S}}}), \mathbf{y}_0)] \quad (182)$$

$$\leq \epsilon + \sum_{S \subseteq \mathcal{B}} 2^{nR_{S,\{0\}}} 2^{-n \cdot \Delta_{m+1,n} (I(U_S^{(m+1)}; Y_0^{(m+1)}, U_{\bar{S}}^{(m+1)}) - \epsilon')} \quad (183)$$

The total cardinality of the case $(\tilde{w}_{r_S} \neq w_{r_S})$ is bounded by $2^{nR_{S,\{0\}}}$ since $\tilde{w}_{r_S}$ is uniquely specified with $\tilde{w}_{S,\{0\}}$ if $w_{\bar{S},\{0\}}$ is given.

Since $\epsilon > 0$ is arbitrary, with the conditions of Theorem 6, a proper choice of $\{R_{0,i:1}\}$ and the AEP property, we can make the right hand sides of (177), (179), (181) and (183) tend to 0 as $n \rightarrow \infty$. By

Fenchel-Bunt's theorem in [12], it is sufficient to restrict $|\mathcal{Q}| \leq 2^{2m} + 2^m$ since 2^{2m} inequalities are from (19) and 2^m inequalities are from (20). ■

APPENDIX D

PROOF OF THEOREM 7

Proof: Random code generation: For simplicity of exposition only, we take $|\mathcal{Q}| = 1$. For all $i \in [1, m]$, nodes 0 and i divide $w_{0,i}$ and $w_{i,0}$ into K blocks, then nodes 0 and i have message set $\{w_{0,i|(1)}, w_{0,i|(2)}, \dots, w_{0,i|(K)}\}$ and $\{w_{i,0|(1)}, w_{i,0|(2)}, \dots, w_{i,0|(K)}\}$, respectively. Then we generate a partition of $\mathcal{S}_{0,i}$ randomly by independently assigning every index $w_{0,i|(k)} \in \mathcal{S}_{0,i}$ to a set $\mathcal{S}_{0,i}(h)$, with a uniform distribution over the indices $h \in \{0, \dots, \lfloor 2^{nR_{0,i:1}} \rfloor - 1\} := \mathcal{S}_{0,i:1}$. We denote by $s_{0,i}(w_{0,i|(k)})$ the index h of $\mathcal{S}_{0,i}(h)$ to which $w_{0,i|(k)}$ belongs.

1) Phase $j \in [1, m]$: Generate random $(n \cdot \Delta_{j,n})$ -length sequences

- $\mathbf{v}_{0i}^{(j)}(w_{0,i:2})$ with $p^{(j)}(\mathbf{v}_{0i})$, $w_{0,i:2} \in \{0, 1, \dots, \lfloor 2^{nR_{0,i:2}} \rfloor - 1\} := \mathcal{S}_{0,i:2}$, where

$$p^{(j)}(\mathbf{v}_{0i}) = \begin{cases} \frac{1}{\|A^{(j)}(V_{0i})\|}, & \mathbf{v}_{0i} \in A^{(j)}(V_{0i}) \\ 0, & \text{otherwise.} \end{cases} \quad (184)$$

For convenience of analysis we define $R_{0,i:3} = \sum_{j \in \mathcal{J}_i} \Delta_j I(V_{0i}^{(j)}; Y_i^{(j)} | V_{j2}^{(j)}) + \sum_{j \notin \mathcal{J}_i} \Delta_j I(V_{0i}^{(j)}; Y_i^{(j)})$ and take $R_{0,i:2} = R_{0,i:1} + R_{0,i:3} - \epsilon'$. Then we define bin $B_h^{0i} := \{w_{0,i:2} | w_{0,i:2} \in [h \cdot \lfloor 2^{n(R_{0,i:3} + R_{0,i:1} - R_{0,i} - \epsilon')} \rfloor, (h+1) \cdot \lfloor 2^{n(R_{0,i:3} + R_{0,i:1} - R_{0,i} - \epsilon')} \rfloor - 1]\}$ for $h \in \{0, 1, \dots, \lfloor 2^{nR_{0,i}} \rfloor - 1\}$.

- $\mathbf{v}_{j1}^{(j)}(w_{j,0:1})$ with $p^{(j)}(\mathbf{v}_{j1})$, $w_{j,0:1} \in \{0, 1, \dots, \lfloor 2^{nR_{j,0:1}} \rfloor - 1\} := \mathcal{S}_{j,0:1}$, where

$$p^{(j)}(\mathbf{v}_{j1}) = \begin{cases} \frac{1}{\|A^{(j)}(V_{j1})\|}, & \mathbf{v}_{j1} \in A^{(j)}(V_{j1}) \\ 0, & \text{otherwise,} \end{cases} \quad (185)$$

and $\mathbf{v}_{j2}^{(j)}(w_{\{j\},\mathcal{B}:1})$ with $p^{(j)}(\mathbf{v}_{j2})$, $w_{\{j\},\mathcal{B}:1} \in \{0, 1, \dots, \lfloor 2^{nR_{\{j\},\mathcal{B}:1}} \rfloor - 1\} := \mathcal{S}_{\{j\},\mathcal{B}:1}$, where

$$p^{(j)}(\mathbf{v}_{j2}) = \begin{cases} \frac{1}{\|A^{(j)}(V_{j2})\|}, & \mathbf{v}_{j2} \in A^{(j)}(V_{j2}) \\ 0, & \text{otherwise.} \end{cases} \quad (186)$$

and $R_{j,0:1} = \Delta_j I(V_{j1}^{(j)}; Y_r^{(j)}) - 4\epsilon$, $R_{\{j\},\mathcal{B}:1} = R_{\{j\},\mathcal{B}} + \Delta_j I(V_{j2}^{(j)}; Y_{\mathcal{T}_{\min}}^{(j)}) - \Delta_{m+1} I(Y_j^{(m+1)}; \hat{Y}_j^{(m+1)} | Y_{\mathcal{T}_{\min}}^{(m+1)}) - 4\epsilon$. Then we define bin $B_h^{j1} := \{w_{j,0:1} | w_{j,0:1} \in [h \cdot \lfloor 2^{n(\Delta_j I(V_{j1}^{(j)}; Y_r^{(j)}) - R_{j,0} - \epsilon')} \rfloor, (h+1) \cdot \lfloor 2^{n(\Delta_j I(V_{j1}^{(j)}; Y_r^{(j)}) - R_{j,0} - \epsilon')} \rfloor - 1]\}$ for $h \in \{0, 1, \dots, \lfloor 2^{nR_{j,0}} \rfloor - 1\}$. Similarly, $B_h^{j2} := \{w_{\{j\},\mathcal{B}:1} | w_{\{j\},\mathcal{B}:1} \in [h \cdot \lfloor 2^{n(\Delta_j I(V_{j2}^{(j)}; Y_{\mathcal{T}_{\min}}^{(j)}) - \Delta_{m+1} I(Y_j^{(m+1)}; \hat{Y}_j^{(m+1)} | Y_{\mathcal{T}_{\min}}^{(m+1)}) - \epsilon')} \rfloor, (h+1) \cdot \lfloor 2^{n(\Delta_j I(V_{j2}^{(j)}; Y_{\mathcal{T}_{\min}}^{(j)}) - \Delta_{m+1} I(Y_j^{(m+1)}; \hat{Y}_j^{(m+1)} | Y_{\mathcal{T}_{\min}}^{(m+1)}) - \epsilon')} \rfloor - 1]\}$ for $h \in \{0, 1, \dots, \lfloor 2^{nR_{\{j\},\mathcal{B}}} \rfloor - 1\}$.

2) Phase $m+1$: Generate random $(n \cdot \Delta_{m+1,n})$ -length sequences

- $\mathbf{u}_i^{(m+1)}(w_{r_i})$ with $p^{(m+1)}(\mathbf{u}_i)$, $w_{r_i} \in \{0, 1, \dots, \lfloor 2^{nR_{r_i}} \rfloor - 1\} := \mathcal{S}_{r_i}$, where

$$p^{(m+1)}(\mathbf{u}_i) = \begin{cases} \frac{1}{\|A^{(m+1)}(U_i)\|}, & \mathbf{u}_i \in A^{(m+1)}(U_i) \\ 0, & \text{otherwise.} \end{cases} \quad (187)$$

and $R_{r_i} = \max\{R_{0,i:1}, R_{i,0}\} + (\Delta_{m+1}I(U_i^{(m+1)}; Y_i^{(m+1)}, \hat{Y}_{\mathcal{J}_i}^{(m+1)}) - 4\epsilon - R_{0,i:1})$.

and define bin $C_h^i := \{w_{r_i} | w_{r_i} \in [h \cdot \lfloor 2^{n(\Delta_{m+1}I(U_i^{(m+1)}; Y_i^{(m+1)}, \hat{Y}_{\mathcal{J}_i}^{(m+1)}) - R_{0,i:1} - 4\epsilon) \rfloor}, (h+1) \cdot \lfloor 2^{n(\Delta_{m+1}I(U_i^{(m+1)}; Y_i^{(m+1)}, \hat{Y}_{\mathcal{J}_i}^{(m+1)}) - R_{0,i:1} - 4\epsilon) \rfloor} - 1]\}$ for $h \in \{0, 1, \dots, \lfloor 2^{n \max\{R_{0,i:1}, R_{i,0}\}} \rfloor - 1\}$.

Encoding: In slot k ,

- 1) To transmit $(w_{0,1|(k)}, \dots, w_{0,m|(k)})$, node 0 picks $(w_{0,1:2}, \dots, w_{0,m:2}) \in \bigotimes_{i=1}^m B_{w_{0,i|(k)}}^{0i}$ such that $\mathbf{v}_{0S}^{(j)}(w_{\{0\},S:2}) \in A^{(j)}(V_{0S})$, $\forall j \in [1, m]$, $S \subseteq \mathcal{B}$, $|S| > 1$. Such a $(w_{0,1:2}, \dots, w_{0,m:2})$ exists with high probability if

$$\sum_{i \in S} (R_{0,i} - R_{0,i:1}) < \sum_{i \in S} \left(\sum_{j \in \mathcal{J}_i} \Delta_j I(V_{0i}^{(j)}; Y_i^{(j)} | V_{j2}^{(i)}) - \Delta_j I(V_{0i}^{(j)}; V_{0S(i)}^{(j)}) + \sum_{j \notin \mathcal{J}_i} \Delta_j I(V_{0i}^{(j)}; Y_i^{(j)}) - \Delta_j I(V_{0i}^{(j)}; V_{0S(i)}^{(j)}) \right) - \delta(\epsilon) \quad (188)$$

for $S \subseteq \mathcal{B}$, $|S| > 1$ from Lemma 21. Then node 0 finds a $\mathbf{x}_0^{(i)}$ jointly typical with

$(\mathbf{v}_{01}^{(i)}(w_{0,1:2}), \dots, \mathbf{v}_{0m}^{(i)}(w_{0,m:2}))$ and designate it as the codeword corresponding to $(w_{0,1|(k)}, \dots, w_{0,m|(k)})$ for all $i \in [1, m]$. Node 0 sends $\mathbf{x}_0^{(i)}(w_{0,1|(k)}, \dots, w_{0,m|(k)})$ during phase i .

- 2) Node $j \in \mathcal{B}$ compresses $\mathbf{y}_j^{(m+1)}$ to $\hat{\mathbf{y}}_j^{(m+1)}(w_{\{j\},\mathcal{B}|(k)})$ if there exists a $w_{\{j\},\mathcal{B}|(k)}$ such that $(\mathbf{y}_j^{(m+1)}, \hat{\mathbf{y}}_j^{(m+1)}(w_{\{j\},\mathcal{B}|(k)}))$ is in the jointly typical set at the end of phase $m+1$ in the slot k . There exists such a $w_{\{j\},\mathcal{B}|(k)}$ with high probability if

$$R_{\{j\},\mathcal{B}} = \Delta_{m+1,n}I(Y_j^{(m+1)}; \hat{Y}_j^{(m+1)}) + \epsilon \quad (189)$$

and n is sufficiently large.

To transmit $(w_{j,0|(k)}, w_{\{j\},\mathcal{B}|(k-1)})$, node j picks $(w_{j,0:1}, w_{\{j\},\mathcal{B}:1})$ such that

$(\mathbf{v}_{j1}^{(j)}(w_{j,0:1}), \mathbf{v}_{j2}^{(j)}(w_{\{j\},\mathcal{B}:1})) \in A^{(j)}(V_{j1}V_{j2})$ and $(w_{j,0:1}, w_{\{j\},\mathcal{B}:1}) \in B_{w_{j,0|(k)}}^{j1} \times B_{w_{\{j\},\mathcal{B}|(k-1)}}^{j2}$. Such a $(w_{j,0:1}, w_{\{j\},\mathcal{B}:1})$ exists with high probability if

$$R_{j,0:1} + \Delta_{m+1}I(Y_j^{(m+1)}; \hat{Y}_j^{(m+1)} | Y_{\mathcal{T}_j^{\min}}^{(m+1)}) < \Delta_j I(V_{j1}^{(j)}; Y_r^{(j)}) + \Delta_j I(V_{j2}^{(j)}; Y_{\mathcal{T}_j^{\min}}^{(j)}) - \Delta_j I(V_{j1}^{(j)}; V_{j2}^{(j)}) - \delta(\epsilon) \quad (190)$$

from Lemma 21. Then node j finds a $\mathbf{x}_j^{(j)}$ jointly typical with $(\mathbf{v}_{j1}^{(j)}(w_{j,0:1}), \mathbf{v}_{j2}^{(j)}(w_{\{j\},\mathcal{B}:1}))$ and designate it as the codeword corresponding to $(w_{j,0|(k)}, w_{\{j\},\mathcal{B}|(k-1)})$. Node j sends $\mathbf{x}_j^{(j)}(w_{j,0|(k)}, w_{\{j\},\mathcal{B}|(k-1)})$ during phase j .

- 3) Relay r estimates $\hat{w}_{0,i|(k)}$ and $\hat{w}_{i,0|(k)}$ after phase m using jointly typical decoding, then constructs $w_i = \hat{w}_{0,i:1} \oplus \hat{w}_{i,0|(k)}$. To transmit a pair of messages $(w_1, \dots, w_m)$, pick a pair $(w_{r_1}, \dots, w_{r_m}) \in \bigotimes_{i=1}^m C_{w_i}^i$ such that $\mathbf{u}_S^{(m+1)}(w_{r_S}) \in A^{(m+1)}(U_S), \forall S \subseteq \mathcal{B}, |S| > 1$. Such a $(w_{r_1}, \dots, w_{r_m})$ exists with high probability if

$$\sum_{i \in S} R_{0,i:1} < \sum_{i \in S} \Delta_{m+1} I(U_i^{(m+1)}; Y_i^{(m+1)}, \hat{Y}_{\mathcal{J}_i}^{(m+1)}) - \Delta_{m+1} I(U_i^{(m+1)}; U_{S(i)}^{(m+1)}) - |S|\epsilon - \delta(\epsilon) \quad (191)$$

for $S \subseteq \mathcal{B}, |S| > 1$ from Lemma 21. Then the relay finds a $\mathbf{x}_r^{(m+1)}$ jointly typical with $(\mathbf{u}_1^{(m+1)}(w_{r_1}), \dots, \mathbf{u}_m^{(m+1)}(w_{r_m}))$ and designate it as the codeword corresponding to $(w_1, \dots, w_m)$. Relay r sends $\mathbf{x}_r^{(m+1)}(w_1, \dots, w_m)$ during phase $m+1$.

Decoding: For all $i \in [1, m]$,

- 1) Node 0 estimates $\tilde{w}_{i,0|(k)}$ after phase $m+1$ using jointly typical decoding. Since $w_i = w_{0,i:1} \oplus w_{i,0|(k)}$ and 0 knows $w_{0,i|(k)}$, node 0 can reduce the number of possible $w_{i,0|(k)}$.
- 2) Node i decodes $\tilde{w}_{\{h\},\mathcal{B}|\{k-1\}}$ after phase h if there exists a unique $\tilde{w}_{\{h\},\mathcal{B}|\{k-1\}}$ such that $(\mathbf{v}_{h2}^{(h)}(\tilde{w}_{\{h\},\mathcal{B}|\{k-1\}}), \mathbf{y}_i^{(h)}) \in A^{(h)}(V_{h2}Y_i)$ and $(\mathbf{y}_i^{(m+1)}, \hat{\mathbf{y}}_h^{(m+1)}(\tilde{w}_{\{h\},\mathcal{B}|\{k-1\}})) \in A^{(m+1)}(Y_i \hat{Y}_h)$ for $h \in \mathcal{J}_i$. Then, node i estimates $\tilde{w}_{r_i}$ of $k-1$ slot after phase $m+1$ using jointly typical sequences $(\mathbf{u}_r^{(m+1)}, \mathbf{y}_i^{(m+1)}, \mathbf{y}_{\mathcal{J}_i}^{(m+1)})$. Similar to the case of node 0, node i can reduce the cardinality of w_{r_i} to $2^{n(\Delta_{m+1} I(U_i^{(m+1)}; Y_i^{(m+1)}, \hat{Y}_{\mathcal{J}_i}^{(m+1)}) - 4\epsilon)}$ and node i decodes $\tilde{w}_{0,i:1}$ from the bin index of $\tilde{w}_{r_i}$. Then, node i estimates $\tilde{w}_{0,i:2}$ using jointly typical decoding of the sequences $(\mathbf{v}_{0i}^{(j)}(\tilde{w}_{0,i:2}), \mathbf{v}_{j2}^{(j)}(w_{\{j\},\mathcal{B}:1}), \mathbf{y}_i^{(j)})$ for all $j \in \mathcal{J}_i$ and $(\mathbf{v}_{0i}^{(j)}(\tilde{w}_{0,i:2}), \mathbf{y}_i^{(j)})$ for all $j \notin \mathcal{J}_i$. Since node i knows the bin index $s_{\tilde{w}_{0,i}}(\tilde{w}_{0,i|(k-1)})$ as $\tilde{w}_{0,i:1}$, it can reduce the cardinality of $w_{0,i:2}$ to $2^{n(\sum_{j \in \mathcal{J}_i} \Delta_j I(V_{0i}^{(j)}; Y_i^{(j)} | V_{j2}^{(j)}) + \sum_{j \notin \mathcal{J}_i} \Delta_j I(V_{0i}^{(j)}; Y_i^{(j)}) - \epsilon')}$. After decoding $\tilde{w}_{0,i:2}$, node i finally decodes $\tilde{w}_{0,i|(k-1)}$ from the bin index of $\tilde{w}_{0,i:2}$.

Error analysis:

$$P[E] = P[E_{enc} \cup E_{dec}] \leq P[E_{enc}] + P[E_{dec}] \quad (192)$$

$$\leq \epsilon + \sum_{i=1}^m P[E_{\{0\},\{i\}}] + P[E_{\{i\},\{0\}}] \quad (193)$$

where E is the entire error event, E_{enc} is the set of encoding error events, and E_{dec} is the set of decoding error events. $P[E_{enc}]$ is upper bounded by sufficiently small number ϵ from (188), (189), (190) and (191).

E_{dec} can be separated by individual decoding error events in each link. Then $\forall j \in [1, m]$,

$$P[E_{\{0\},\{j\}}] \leq P[(\cup_{i=1}^m E_{\{0,i\},\{r\}}^{(i)}) \cup (\cup_{h \in \mathcal{J}_j} E_{\{h\},\{j\}}^{(h)}) \cup E_{\{r\},\{j\}}^{(m+1)} \cup E_{\{0\},\{j\}}^{(m+1)}] \quad (194)$$

$$\begin{aligned} &\leq P[\cup_{i=1}^m E_{\{0,i\},\{r\}}^{(i)}] + P[\cup_{h \in \mathcal{J}_j} E_{\{h\},\{j\}}^{(h)} | \cap_{i=1}^m \bar{E}_{\{0,i\},\{r\}}^{(i)}] + \\ &\quad P[E_{\{r\},\{j\}}^{(m+1)} | (\cap_{h \in \mathcal{J}_j} \bar{E}_{\{h\},\{j\}}^{(h)}) \cap (\cap_{i=1}^m \bar{E}_{\{0,i\},\{r\}}^{(i)})] + \\ &\quad P[E_{\{0\},\{j\}}^{(m+1)} | (\cap_{h \in \mathcal{J}_j} \bar{E}_{\{h\},\{j\}}^{(h)}) \cap (\cap_{i=1}^m \bar{E}_{\{0,i\},\{r\}}^{(i)}) \cap \bar{E}_{\{r\},\{j\}}^{(m+1)}] \end{aligned} \quad (195)$$

$$P[E_{\{j\},\{0\}}] \leq P[(\cup_{i=1}^m E_{\{0,i\},\{r\}}^{(i)}) \cup E_{\{r\},\{0\}}^{(m+1)}] \quad (196)$$

$$\leq P[\cup_{i=1}^m E_{\{0,i\},\{r\}}^{(i)}] + P[E_{\{r\},\{0\}}^{(m+1)} | \cap_{i=1}^m \bar{E}_{\{0,i\},\{r\}}^{(i)}] \quad (197)$$

Now we will show that $P[\cup_{i=1}^m E_{\{0,i\},\{r\}}^{(i)}]$, $P[\cup_{h \in \mathcal{J}_j} E_{\{h\},\{j\}}^{(h)} | \cap_{i=1}^m \bar{E}_{\{0,i\},\{r\}}^{(i)}]$, $P[E_{\{r\},\{j\}}^{(m+1)} | (\cap_{h \in \mathcal{J}_j} \bar{E}_{\{h\},\{j\}}^{(h)}) \cap (\cap_{i=1}^m \bar{E}_{\{0,i\},\{r\}}^{(i)})]$, $P[E_{\{0\},\{j\}}^{(m+1)} | (\cap_{h \in \mathcal{J}_j} \bar{E}_{\{h\},\{j\}}^{(h)}) \cap (\cap_{i=1}^m \bar{E}_{\{0,i\},\{r\}}^{(i)}) \cap \bar{E}_{\{r\},\{j\}}^{(m+1)}]$ and $P[E_{\{r\},\{0\}}^{(m+1)} | \cap_{i=1}^m \bar{E}_{\{0,i\},\{r\}}^{(i)}]$ tend to zero as $n \rightarrow \infty$. For the convenience of analysis we define $B_R^{0i}(w_{0,i:1}) = \cup_{w_{0,i} \in \mathcal{S}_{0,i}(w_{0,i:1})} B_{w_{0,i}}^{0i}$ and $C_R^i(w_{i,0}) = \cup_{w_{0,i:1} \in \mathcal{S}_{0,i:1} C_{w_{0,i:1} \oplus w_{i,0}}^i$. Similarly, $B_R^{i2}(j) = \cup_{w_{\{i\},\mathcal{B}} \in T_i^j} B_{w_{\{i\},\mathcal{B}}}^{i2}$ such that $T_i^j = \{w_{\{i\},\mathcal{B}} | (\mathbf{y}_j^{(m+1)}, \hat{\mathbf{y}}_i^{(m+1)}(w_{\{i\},\mathcal{B}})) \in A^{(m+1)}(Y_j, \hat{Y}_i)\}$.

$$\begin{aligned} &P[\cup_{i=1}^m E_{\{0,i\},\{r\}}^{(i)}] \\ &\leq \sum_{i=1}^m \left(P[\bar{D}^{(i)}(\mathbf{v}_{0\mathcal{B}}(w_{\{0\},\mathcal{B}:2}), \mathbf{v}_{i1}(w_{i,0:1}), \mathbf{y}_r)] + P[\cup_{\tilde{w}_{i,0:1} \neq w_{i,0:1}} D^{(i)}(\mathbf{v}_{i1}(\tilde{w}_{i,0:1}), \mathbf{y}_r)] \right) + \\ &\quad \sum_{S \subseteq \mathcal{B}} P \left[\cup_{\tilde{w}_{\{0\},S}} (\cap_{i=1}^m D^{(i)}(\mathbf{v}_{0S}(\tilde{w}_{\{0\},S:2}), \mathbf{v}_{0\bar{S}}(w_{\{0\},\bar{S}:2}), \mathbf{v}_{i1}(w_{i,0:1}), \mathbf{y}_r)) \right] \end{aligned} \quad (198)$$

$$\leq m \cdot \epsilon + \sum_{i=1}^m 2^{n(R_{i,0:1} - \Delta_{i,n} I(V_{i1}^{(i)}; Y_r^{(i)}) + 3\epsilon)} + \sum_{S \subseteq \mathcal{B}} 2^{n(R_{\{0\},S} - \sum_{i=1}^m \Delta_{i,n} I(V_{0S}^{(i)}; Y_r^{(i)}, V_{0\bar{S}}^{(i)} | V_{i1}^{(i)})) + \epsilon'} \quad (199)$$

The total cardinality of the case $(\tilde{w}_{\{0\},S:2} \neq w_{\{0\},S:2})$ is bounded by $2^{nR_{\{0\},S}}$ since $\tilde{w}_{\{0\},S:2}$ is uniquely specified with $\tilde{w}_{\{0\},S}$ if $w_{\{0\},\bar{S}:2}$ is given.

$$P[\cup_{h \in \mathcal{J}_j} E_{\{h\},\{j\}}^{(h)} | \cap_{i=1}^m \bar{E}_{\{0,i\},\{r\}}^{(i)}] \leq \sum_{h \in \mathcal{J}_j} P[E_{\{h\},\{j\}}^{(h)} | \cap_{i=1}^m \bar{E}_{\{0,i\},\{r\}}^{(i)}] \quad (200)$$

Also,

$$\begin{aligned} &P[E_{\{h\},\{j\}}^{(h)} | \cap_{i=1}^m \bar{E}_{\{0,i\},\{r\}}^{(i)}] \leq P[\bar{D}^{(h)}(\mathbf{v}_{h2}(w_{h,j}), \mathbf{y}_j)] + \\ &\quad P[\cup_{\tilde{w}_{\{h\},\mathcal{B}:1} \in B_R^{h2}(j)} D^{(h)}(\mathbf{v}_{h2}(\tilde{w}_{\{h\},\mathcal{B}:1}), \mathbf{y}_j)] \end{aligned} \quad (201)$$

$$\leq \epsilon + |B_R^{h2}(j)| \cdot 2^{-n(\Delta_{h,n} I(V_{h2}^{(h)}; Y_j^{(h)}) - 3\epsilon)} \quad (202)$$

and $|B_R^{h2}(j)| = 2^{n(\Delta_{m+1}I(Y_h^{(m+1)}; \hat{Y}_h^{(m+1)}|Y_j^{(m+1)}) + \Delta_h I(V_{h2}^{(h)}; Y_{\mathcal{T}_{\min}}^{(h)}) - \Delta_{m+1}I(Y_h^{(m+1)}; \hat{Y}_h^{(m+1)}|Y_{\mathcal{T}_{\min}}^{(m+1)}) - 4\epsilon)}$.

$$\begin{aligned} P[E_{\{r\},\{j\}}^{(m+1)} | (\cap_{h \in \mathcal{J}_j} \bar{E}_{\{h\},\{j\}}^{(h)}) \cap (\cap_{i=1}^m \bar{E}_{\{0,i\},\{r\}}^{(i)})] \\ \leq P[\bar{D}^{(m+1)}(\mathbf{u}_j(w_{r_j}), \mathbf{y}_j)] + P[\cup_{\tilde{w}_{r_j} \in C_R^j(w_{j,0})} D^{(m+1)}(\mathbf{u}_j(\tilde{w}_{r_j}), \mathbf{y}_j, \hat{\mathbf{y}}_{\mathcal{J}_j})] \end{aligned} \quad (203)$$

$$\leq \epsilon + |C_R^j(w_{j,0})| \cdot 2^{-n(\Delta_{m+1,n}I(U_j^{(m+1)}; Y_j^{(m+1)}; \hat{Y}_{\mathcal{J}_j}^{(m+1)}) - 3\epsilon)} \quad (204)$$

$$\begin{aligned} P[E_{\{0\},\{j\}}^{(m+1)} | (\cap_{h \in \mathcal{J}_j} \bar{E}_{\{h\},\{j\}}^{(h)}) \cap (\cap_{i=1}^m \bar{E}_{\{0,i\},\{r\}}^{(i)}) \cap \bar{E}_{\{r\},\{j\}}^{(m+1)}] \\ \leq \sum_{i \neq j} P[\bar{D}^{(i)}(\mathbf{v}_{0j}(w_{0,j:2}), \mathbf{y}_j)] + \\ P \left[\cup_{\tilde{w}_{0,j:2} \in B_R^j(w_{0,i:1})} \left(\cap_{i \in \mathcal{J}_j} D^{(i)}(\mathbf{v}_{0j}(\tilde{w}_{0,j:2}), \mathbf{v}_{i2}(w_{\{i\},\mathcal{B}:1}), \mathbf{y}_j) \cap_{i \notin \mathcal{J}_j} D^{(i)}(\mathbf{v}_{0j}(\tilde{w}_{0,j:2}), \mathbf{y}_j) \right) \right] \end{aligned} \quad (205)$$

$$\leq (m-1)\epsilon + |B_R^i(w_{0,i:1})| \cdot 2^{-n(\sum_{i \in \mathcal{J}_j} \Delta_{i,n}I(V_{0j}^{(i)}; Y_j^{(i)}|V_{i2}^{(i)}) + \sum_{i \notin \mathcal{J}_j} \Delta_{i,n}I(V_{0j}^{(i)}; Y_j^{(i)}) - \epsilon'')} \quad (206)$$

$$\begin{aligned} P[E_{\{r\},\{0\}}^{(m+1)} | \cap_{j=1}^m \bar{E}_{\{0,j\},\{r\}}^{(j)}] \leq P[\bar{D}^{(m+1)}(\mathbf{u}_{\mathcal{B}}(w_{r_{\mathcal{B}}}), \mathbf{y}_0)] + \\ \sum_{S \subseteq \mathcal{B}} P[\cup_{\tilde{w}_{S,\{0\}} \neq w_{S,\{0\}}} D^{(m+1)}(\mathbf{u}_S(\tilde{w}_{r_S}), \mathbf{u}_{\bar{S}}(w_{r_{\bar{S}}}), \mathbf{y}_0)] \end{aligned} \quad (207)$$

$$\leq \epsilon + \sum_{S \subseteq \mathcal{B}} 2^{nR_{S,\{0\}}} 2^{-n \cdot \Delta_{m+1,n}(I(U_S^{(m+1)}; Y_0^{(m+1)}; U_S^{(m+1)}) - \epsilon')} \quad (208)$$

The total cardinality of the case $(\tilde{w}_{r_S} \neq w_{r_S})$ is bounded by $2^{nR_{S,\{0\}}}$ since $\tilde{w}_{r_S}$ is uniquely specified with $\tilde{w}_{S,\{0\}}$ if $w_{\bar{S},\{0\}}$ is given.

Since $\epsilon > 0$ is arbitrary, with the conditions of Theorem 7 and the AEP property, we can make the right hand sides of (199), (202), (204), (206) and (208) tend to 0 as $n \rightarrow \infty$. By Carathéodory theorem in [12], it is sufficient to restrict $|\mathcal{Q}| \leq 2^{m+1} + m^2 + m + 2$ since 2^m inequality is from (22), m inequalities are from (23), 2^m inequalities are from (24), m inequalities are from (26) and $m(m-1)$ inequalities are from (27). $\blacksquare$

APPENDIX E

PROOF OF THEOREM 10

Proof: Random code generation: For all $i \in [1, m]$, first we generate a partition of $\mathcal{S}_{0,i}$ randomly by independently assigning every index $w_{0,i} \in \mathcal{S}_{0,i}$ to a set $\mathcal{S}_{0,i}(j)$, with a uniform distribution over the indices $j \in \{0, \dots, \lfloor 2^{nR_{0,i:1}} \rfloor - 1\} := \mathcal{S}_{0,i:1}$. We denote by $s_{0,i}(w_{0,i})$ the index j of $\mathcal{S}_{0,i}(j)$ to which $w_{0,i}$ belongs. Similarly, we generate a partition of $\mathcal{S}_{i,0}$ with the cardinality $2^{nR_{i,0:1}}$.

1) Phase 1: Generate random $(n \cdot \Delta_{1,n})$ -length sequences

- $\mathbf{v}_{0i}^{(1)}(w_{0,i:2})$ with $p^{(1)}(\mathbf{v}_{0i})$, $w_{0,i:2} \in \{0, 1, \dots, \lfloor 2^{nR_{0,i:2}} \rfloor - 1\} := \mathcal{S}_{0,i:2}$, where

$$p^{(1)}(\mathbf{v}_{0i}) = \begin{cases} \frac{1}{\|A^{(1)}(V_{0i})\|}, & \mathbf{v}_{0i} \in A^{(1)}(V_{0i}) \\ 0, & \text{otherwise.} \end{cases} \quad (209)$$

and $R_{0,i:2} = R_{0,i:1} + \Delta_1 I(V_{0i}^{(1)}; Y_i^{(1)}) - 4\epsilon$. Then we define bin $B_j^i := \{w_{0,i:2} | w_{0,i:2} \in [j \cdot \lfloor 2^{n(\Delta_1 I(V_{0i}^{(1)}; Y_i^{(1)}) + R_{0,i:1} - R_{0,i} - 4\epsilon) \rfloor}, (j+1) \cdot \lfloor 2^{n(\Delta_1 I(V_{0i}^{(1)}; Y_i^{(1)}) + R_{0,i:1} - R_{0,i} - 4\epsilon) \rfloor - 1] \}$ for $j \in \{0, 1, \dots, \lfloor 2^{nR_{0,i}} \rfloor - 1\}$.

- 2) Phase $i + 1$: Generate random $(n \cdot \Delta_{i+1,n})$ -length sequences

- $\mathbf{x}_i^{(i+1)}(w_{i,0})$ i.i.d. with $p^{(i+1)}(x_i)$, $w_{i,0} \in \mathcal{S}_{i,0}$

- 3) Phase $m + 2$: Generate random $(n \cdot \Delta_{m+2,n})$ -length sequences

- $\mathbf{u}_i^{(m+2)}(w_{r_i})$ with $p^{(m+2)}(\mathbf{u}_i)$, $w_{r_i} \in \{0, 1, \dots, \lfloor 2^{nR_{r_i}} \rfloor - 1\} := \mathcal{S}_{r_i}$, where

$$p^{(m+2)}(\mathbf{u}_i) = \begin{cases} \frac{1}{\|A^{(m+2)}(U_i)\|}, & \mathbf{u}_i \in A^{(m+2)}(U_i) \\ 0, & \text{otherwise.} \end{cases} \quad (210)$$

and $R_{r_i} = \max\{R_{0,i:1}, R_{i,0:1}\} + (\Delta_{m+2} I(U_i^{(m+2)}; Y_i^{(m+2)}) - 4\epsilon - R_{0,i:1})$.

and define bin $C_j^i := \{w_{r_i} | w_{r_i} \in [j \cdot \lfloor 2^{n(\Delta_{m+2} I(U_i^{(m+2)}; Y_i^{(m+2)}) - R_{0,i:1} - 4\epsilon) \rfloor},$

$(j+1) \cdot \lfloor 2^{n(\Delta_{m+2} I(U_i^{(m+2)}; Y_i^{(m+2)}) - R_{0,i:1} - 4\epsilon) \rfloor - 1] \}$ for $j \in \{0, 1, \dots, \lfloor 2^{n \max\{R_{0,i:1}, R_{i,0:1}\}} \rfloor - 1\}$.

Encoding: For all $i \in [1, m]$,

- 1) During phase 1, to transmit $(w_{0,1}, \dots, w_{0,m})$, node 0 picks $(w_{0,1:2}, \dots, w_{0,m:2}) \in \bigotimes_{i=1}^m B_{w_{0,i}}^i$ such that $\mathbf{v}_{0S}^{(1)}(w_{\{0\},S:2}) \in A^{(1)}(V_{0S})$, $\forall S \in \mathcal{B}$, $|S| > 1$. Such a $(w_{0,1:2}, \dots, w_{0,m:2})$ exists with high probability if

$$\sum_{i \in S} (R_{0,i} - R_{0,i:1}) < \sum_{i \in S} \Delta_1 I(V_{0i}^{(1)}; Y_i^{(1)}) - \Delta_1 I(V_{0i}^{(1)}; V_{0S(i)}^{(1)}) - |S|\epsilon - \delta(\epsilon) \quad (211)$$

for $S \subseteq \mathcal{B}$, $|S| > 1$ from Lemma 21. Then node 0 finds a $\mathbf{x}_0^{(1)}$ jointly typical with

$(\mathbf{v}_{01}^{(1)}(w_{0,1:2}), \dots, \mathbf{v}_{0m}^{(1)}(w_{0,m:2}))$ and designate it as the codeword corresponding to $(w_{0,1}, \dots, w_{0,m})$.

Node 0 sends $\mathbf{x}_0^{(1)}(w_{0,1}, \dots, w_{0,m})$ during phase 1.

- 2) During phase $i + 1$ encoder of terminal node i sends the codeword $\mathbf{x}_i^{(i+1)}(w_{i,0})$.

- 3) Relay r estimates $\hat{w}_{0,i}$ and $\hat{w}_{i,0}$ after phase $m + 1$ using jointly typical decoding, then constructs $w_i = \hat{w}_{0,i:1} \oplus \hat{w}_{i,0:1}$. To transmit a pair of messages $(w_1, \dots, w_m)$, pick a pair $(w_{r_1}, \dots, w_{r_m}) \in \bigotimes_{i=1}^m C_{w_i}^i$ such that $\mathbf{u}_S^{(m+2)}(w_{r_S}) \in A^{(m+2)}(U_S)$, $\forall S \in \mathcal{B}$, $|S| > 1$. Such a $(w_{r_1}, \dots, w_{r_m})$ exists with high probability if

$$\sum_{i \in S} R_{0,i:1} < \sum_{i \in S} \Delta_{m+2} I(U_i^{(m+2)}; Y_i^{(m+2)}) - \Delta_{m+2} I(U_i^{(m+2)}; U_{S(i)}^{(m+2)}) - |S|\epsilon - \delta(\epsilon) \quad (212)$$

for $S \subseteq \mathcal{B}$, $|S| > 1$. from Lemma 21. Then the relay finds a $\mathbf{x}_r^{(m+2)}$ jointly typical with $(\mathbf{u}_1^{(m+2)}(w_{r_1}), \dots, \mathbf{u}_m^{(m+2)}(w_{r_m}))$ and designate it as the codeword corresponding to $(w_1, \dots, w_m)$. Relay r sends $\mathbf{x}_r^{(m+2)}(w_1, \dots, w_m)$ during phase $m + 2$.

Decoding: For all $i \in [1, m]$,

- 1) Node 0 estimates $\tilde{w}_{i,0:1}$ after phase $m + 2$ using jointly typical decoding. Since $w_i = w_{0,i:1} \oplus w_{i,0:1}$ and 0 knows $w_{0,i}$, node 0 can reduce the number of possible w_i . Then node 0 decodes $\tilde{w}_{i,0}$ if there exists a unique $\tilde{w}_{i,0} \in \mathcal{S}_{i,0}(\tilde{w}_{i,0:1})$ such that $(\mathbf{x}_i^{(i+1)}(\tilde{w}_{i,0}), \mathbf{y}_0^{(i+1)}) \in A^{(i+1)}(X_i Y_0)$.
- 2) Node i estimates $\tilde{w}_{r_i}$ after phase $m + 2$ using jointly typical decoding. Similar to the case of node 0, node i can reduce the cardinality of w_{r_i} to $2^{n(\Delta_{m+2} I(U_i^{(m+2)}; Y_i^{(m+2)}) - 4\epsilon)}$ and node i decodes $\tilde{w}_{0,i:1}$ from the bin index of $\tilde{w}_{r_i}$. Then, node i estimates $\tilde{w}_{0,i:2}$ using jointly typical decoding of the sequence $(\mathbf{v}_{0i}^{(1)}(\tilde{w}_{0,i:2}), \mathbf{y}_i^{(1)})$. Since node i knows the bin index $s_{\tilde{w}_{0,i}}(\tilde{w}_{0,i})$ as $\tilde{w}_{0,i:1}$, it can reduce the cardinality of $w_{0,i:2}$ to $2^{n(\Delta_1 I(V_{0i}^{(1)}; Y_i^{(1)}) - 4\epsilon)}$. After decoding $\tilde{w}_{0,i:2}$, node i finally decodes $\tilde{w}_{0,i}$ from the bin index of $\tilde{w}_{0,i:2}$.

Error analysis:

$$P[E] = P[E_{enc} \cup E_{dec}] \leq P[E_{enc}] + P[E_{dec}] \quad (213)$$

$$\leq \epsilon + \sum_{i=1}^m P[E_{\{0\},\{i\}}] + P[E_{\{i\},\{0\}}] \quad (214)$$

where E is the entire error event, E_{enc} is the set of encoding error events, and E_{dec} is the set of decoding error events. $P[E_{enc}]$ is upper bounded by sufficiently small number ϵ from (211) and (212). E_{dec} can be separated by individual decoding error events in each link. Then $\forall i \in [1, m]$,

$$P[E_{\{0\},\{i\}}] \leq P[E_{\{0\},\{r\}}^{(1)} \cup E_{\{r\},\{i\}}^{(m+2)} \cup E_{\{0\},\{i\}}^{(m+2)}] \quad (215)$$

$$\leq P[E_{\{0\},\{r\}}^{(1)}] + P[E_{\{r\},\{i\}}^{(m+2)} | \bar{E}_{\{0\},\{r\}}^{(1)}] + P[E_{\{0\},\{i\}}^{(m+2)} | \bar{E}_{\{0\},\{r\}}^{(1)} \cap \bar{E}_{\{r\},\{i\}}^{(m+2)}] \quad (216)$$

$$P[E_{\{i\},\{0\}}] \leq P[E_{\{i\},\{r\}}^{(i+1)} \cup E_{\{r\},\{0\}}^{(m+2)} \cup E_{\{i\},\{0\}}^{(m+2)}] \quad (217)$$

$$\leq P[E_{\{i\},\{r\}}^{(i+1)}] + P[E_{\{r\},\{0\}}^{(m+2)} | \bar{E}_{\{i\},\{r\}}^{(i+1)}] + P[E_{\{i\},\{0\}}^{(m+2)} | \bar{E}_{\{i\},\{r\}}^{(i+1)} \cap \bar{E}_{\{r\},\{0\}}^{(m+2)}] \quad (218)$$

Also, for the convenience of analysis we define $B_R^i(w_{0,i:1}) = \cup_{w_{0,i} \in \mathcal{S}_{0,i}(w_{0,i:1})} B_{w_{0,i}}^i$ and $C_R^i(w_{i,0:1}) = \cup_{w_{0,i:1} \in \mathcal{S}_{0,i:1} C_{w_{0,i:1} \oplus w_{i,0:1}}^i$. Then,

$$P[E_{\{0\},\{r\}}^{(1)}] \leq P[\bar{D}^{(1)}(\mathbf{v}_{0\mathcal{B}}(w_{\{0\},\mathcal{B}}), \mathbf{y}_r)] + \sum_{S \subseteq \mathcal{B}} P[\cup_{\tilde{w}_{\{0\},S}} D^{(1)}(\mathbf{v}_{0S}(\tilde{w}_{\{0\},S:2}), \mathbf{v}_{0\bar{S}}(\tilde{w}_{\{0\},\bar{S}:2}), \mathbf{y}_r)] \quad (219)$$

$$\leq \epsilon + \sum_{S \subseteq \mathcal{B}} 2^{n(R_{\{0\},S} - \Delta_{1,n}(I(V_{0S}^{(1)}; Y_r^{(1)} V_{0S}) + \epsilon'))} \quad (220)$$

The total cardinality of the case $(\tilde{w}_{\{0\},S:2} \neq w_{\{0\},S:2})$ is bounded by $2^{nR_{\{0\},S}}$ since $\tilde{w}_{\{0\},S:2}$ is uniquely specified with $\tilde{w}_{\{0\},S}$ if $w_{\{0\},\bar{S}:2}$ is given.

$$P[E_{\{r\},\{i\}}^{(m+2)} | \bar{E}_{\{0\},\{r\}}^{(1)}] \leq P[\bar{D}^{(m+2)}(\mathbf{u}_i(w_{r_i}), \mathbf{y}_i)] + P[\cup_{\tilde{w}_{r_i} \in C_R^i(w_{i,0:1})} D^{(m+2)}(\mathbf{u}_i(\tilde{w}_{r_i}), \mathbf{y}_i)] \quad (221)$$

$$\leq \epsilon + |C_R^i(w_{i,0:1})| \cdot 2^{-n(\Delta_{m+2,n} I(U_i^{(m+2)}; Y_i^{(m+2)}) - 3\epsilon)} \quad (222)$$

$$P[E_{\{0\},\{i\}}^{(m+2)} | \bar{E}_{\{0\},\{r\}}^{(1)} \cap \bar{E}_{\{r\},\{i\}}^{(m+2)}] \leq P[\bar{D}^{(1)}(\mathbf{v}_{0i}(w_{0,i:2}), \mathbf{y}_i)] + P[\cup_{\tilde{w}_{0,i:2} \in B_R^i(w_{0,i:1})} D^{(1)}(\mathbf{v}_{0i}(\tilde{w}_{0,i:2}), \mathbf{y}_i)] \quad (223)$$

$$\leq \epsilon + |B_R^i(w_{0,i:1})| \cdot 2^{-n(\Delta_{1,n} I(V_{0i}^{(1)}; Y_i^{(1)}) - 3\epsilon)} \quad (224)$$

$$P[E_{\{i\},\{r\}}^{(i+1)}] \leq P[\bar{D}^{(i+1)}(\mathbf{x}_i(w_{i,0}), \mathbf{y}_r)] + P[\cup_{\tilde{w}_{i,0} \neq w_{i,0}} D^{(i+1)}(\mathbf{x}_i(\tilde{w}_{i,0}), \mathbf{y}_r)] \quad (225)$$

$$\leq \epsilon + 2^{n(R_{i,0} - \Delta_{i+1,n} (I(X_i^{(i+1)}; Y_r^{(i+1)}) + 3\epsilon))} \quad (226)$$

$$P[E_{\{r\},\{0\}}^{(m+2)} | \bar{E}_{\{i\},\{r\}}^{(i+1)}] \leq P[\bar{D}^{(m+2)}(\mathbf{u}_B(w_{r_B}), \mathbf{y}_0)] + \sum_{S \subseteq \mathcal{B}} P[\cup_{\tilde{w}_{S,\{0\}} \neq w_{S,\{0\}}} D^{(m+2)}(\mathbf{u}_S(\tilde{w}_{r_S}), \mathbf{u}_{\bar{S}}(w_{r_{\bar{S}}}), \mathbf{y}_0)] \quad (227)$$

$$\leq \epsilon + \sum_{S \subseteq \mathcal{B}} 2^{nR_{S,\{0\}:1}} 2^{-n \cdot \Delta_{m+2,n} (I(U_S^{(m+2)}; Y_0^{(m+2)}, U_{\bar{S}}^{(m+2)}) - \epsilon')} \quad (228)$$

The total cardinality of the case $(\tilde{w}_{r_S} \neq w_{r_S})$ is bounded by $2^{nR_{S,\{0\}:1}}$ since $\tilde{w}_{r_S}$ is uniquely specified with $\tilde{w}_{S,\{0\}:1}$ if $w_{\bar{S},\{0\}:1}$ is given.

$$P[E_{\{i\},\{0\}}^{(m+2)} | \bar{E}_{\{i\},\{r\}}^{(i+1)} \cap \bar{E}_{\{r\},\{0\}}^{(m+2)}] \leq P[\bar{D}^{(i+1)}(\mathbf{x}_i(w_{i,0}), \mathbf{y}_0)] + P[\cup_{\tilde{w}_{i,0} \neq w_{i,0}} D^{(i+1)}(\mathbf{x}_i(\tilde{w}_{i,0}), \mathbf{y}_0) \cap (\tilde{w}_{i,0} \in S_{i,0}(w_{i,0:1}))] \quad (229)$$

$$\leq \epsilon + 2^{n(R_{i,0} - \Delta_{i+1,n} (I(X_i^{(i+1)}; Y_0^{(i+1)}) - R_{i,0:1} + 3\epsilon))} \quad (230)$$

Since $\epsilon > 0$ is arbitrary, with the conditions of Theorem 10, proper choices of $\{R_{0,i:1}\}$ and $\{R_{i,0:1}\}$ and the AEP property, we can make the right hand sides of (220), (222), (224), (226), (228) and (230) tend to 0 as $n \rightarrow \infty$. ■

APPENDIX F

APPLY EXTENDED MARTON'S BOUND TO THE GAUSSIAN CHANNEL

For convenience of analysis, we define a function as follow:

$$f(\mathbf{a}, \mathbf{b}, \mathbf{c}) := \sum_{i=1}^m a_i b_i c_i \quad (231)$$

where $\mathbf{a}, \mathbf{b}, \mathbf{c}$ are vectors length m . Similar to Costa's setup in [5], we will apply the broadcast scheme in the previous section to the Gaussian channel. We use the following relationship between input signals and auxiliary variables of transmitter a:

$$\mathbf{U}_a = \mathbf{\Lambda}_a \mathbf{V}_a \quad (232)$$

$$X_a = \sum_{i=1}^m V_{ai} \quad (233)$$

where $\mathbf{U}_a$ and $\mathbf{V}_a$ are vectors length m and $\mathbf{\Lambda}_a \in \mathbb{R}^{m \times m}$. Also $V_{ai}'s$ follow the distributions $V_{ai} \sim \mathcal{CN}(0, \beta_{ai}P)$, where $(0 \leq \beta_{ai} \leq 1)$, $\sum_{i=1}^m \beta_{ai} = 1$ and $V_{ai}'s$ are independent. We define $\bar{\lambda}_{ai}$ as the i^{th} row vector of $\mathbf{\Lambda}_a$, i.e., $\bar{\lambda}_{ai} = (\lambda_{ai1}, \lambda_{ai2}, \dots, \lambda_{aim})$ and $\bar{\beta}_a = (\beta_{a1}, \dots, \beta_{am})$.

Now we define some useful functions to evaluate mutual information terms in the Gaussian broadcast channel. We consider two scenarios; the single transmitter case and the double transmitter case. The latter one is only for the multiple access period of the PMABC protocols. We assume that there are two senders a, b and two receivers c and d. Node a has m independent messages and corresponding m auxiliary random variables $U_{ai}'s$. Similarly, Node b constructs $U_{bi}'s$.

1) Single transmitter (when node a is only broadcasting)

$$\begin{aligned} I(U_{ai}; Y_c) &= C \left(\frac{|h_{a,c}|^2 P_a f^2(\bar{\lambda}_{ai}, \bar{1}, \bar{\beta}_a)}{|h_{a,c}|^2 P_a (f(\bar{\lambda}_{ai}, \bar{\lambda}_{ai}, \bar{\beta}_a) - f^2(\bar{\lambda}_{ai}, \bar{1}, \bar{\beta}_a)) + f(\bar{\lambda}_{ai}, \bar{\lambda}_{ai}, \bar{\beta}_a)} \right) \\ &:= C_B(P_a, h_{a,c}, \bar{\lambda}_{ai}, \bar{\beta}_a) \end{aligned} \quad (234)$$

$$\begin{aligned} I(U_{ai}; U_{aj}) &= C \left(\frac{f^2(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\beta}_a)}{f(\bar{\lambda}_{ai}, \bar{\lambda}_{ai}, \bar{\beta}_a) f(\bar{\lambda}_{aj}, \bar{\lambda}_{aj}, \bar{\beta}_a) - f^2(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\beta}_a)} \right) \\ &:= C_{BE}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\beta}_a) \end{aligned} \quad (235)$$

$$\begin{aligned} I(U_{ai}; U_{aj}, U_{ak}) &= C \left(\frac{K_{BE2}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\lambda}_{ak}, \bar{\beta}_a)}{K_{BE1}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\lambda}_{ak}, \bar{\beta}_a) - K_{BE2}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\lambda}_{ak}, \bar{\beta}_a)} \right) \\ &:= C_{BE2}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\lambda}_{ak}, \bar{\beta}_a) \end{aligned} \quad (236)$$

$$\begin{aligned} I(U_{ai}; Y_c, U_{aj}) &= \\ C \left(\frac{|h_{a,c}|^2 K_{C2}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\beta}_a) P_a + K_{C4}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\beta}_a)}{|h_{a,c}|^2 (K_{C1}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\beta}_a) - K_{C2}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\beta}_a)) P_a + (K_{C3}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\beta}_a) - K_{C4}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\beta}_a))} \right) \\ &:= C_C(P_a, h_{a,c}, \bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\beta}_a) \end{aligned} \quad (237)$$

$$\begin{aligned} I(U_{ai}; Y_c, \hat{Y}_d) &= \\ C \left(\frac{f^2(\bar{\lambda}_{ai}, \bar{1}, \bar{\beta}_a) K_{BC2}(P_a, h_{a,c}, h_{a,d}, P_d, \sigma_d)}{f(\bar{\lambda}_{ai}, \bar{\lambda}_{ai}, \bar{\beta}_a) K_{BC1}(P_a, h_{a,c}, h_{a,d}, P_d, \sigma_d) - f^2(\bar{\lambda}_{ai}, \bar{1}, \bar{\beta}_a) K_{BC2}(P_a, h_{a,c}, h_{a,d}, P_d, \sigma_d)} \right) \\ &:= C_{BC}(P_a, h_{a,c}, h_{a,d}, \bar{\lambda}_{ai}, \bar{\beta}_a, P_d, \sigma_d) \end{aligned} \quad (238)$$

where $P_d = E[\hat{Y}_d^2]$, $\sigma_d = E[Y_d \hat{Y}_d]$ and

$$K_{BE1}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\lambda}_{ak}, \bar{\beta}_a) = f(\bar{\lambda}_{ai}, \bar{\lambda}_{ai}, \bar{\beta}_a) f(\bar{\lambda}_{aj}, \bar{\lambda}_{aj}, \bar{\beta}_a) f(\bar{\lambda}_{ak}, \bar{\lambda}_{ak}, \bar{\beta}_a) - f(\bar{\lambda}_{ai}, \bar{\lambda}_{ai}, \bar{\beta}_a) f^2(\bar{\lambda}_{aj}, \bar{\lambda}_{ak}, \bar{\beta}_a) \quad (239)$$

$$K_{CI1}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\lambda}_{bk}, \bar{\beta}_a, \bar{\beta}_b) = f(\bar{\lambda}_{bk}, \bar{\lambda}_{bk}, \bar{\beta}_b) f^2(\bar{\lambda}_{ai}, \bar{1}, \bar{\beta}_a) f(\bar{\lambda}_{aj}, \bar{\lambda}_{aj}, \bar{\beta}_a) + \\ f(\bar{\lambda}_{bk}, \bar{\lambda}_{bk}, \bar{\beta}_b) f^2(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\beta}_a) - 2f(\bar{\lambda}_{bk}, \bar{\lambda}_{bk}, \bar{\beta}_b) f(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\beta}_a) f(\bar{\lambda}_{ai}, \bar{1}, \bar{\beta}_a) f(\bar{\lambda}_{aj}, \bar{1}, \bar{\beta}_a) \quad (257)$$

$$K_{CI2}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\lambda}_{bk}, \bar{\beta}_a, \bar{\beta}_b) = f^2(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\beta}_a) (f(\bar{\lambda}_{bk}, \bar{\lambda}_{bk}, \bar{\beta}_b) - f^2(\bar{\lambda}_{bk}, \bar{1}, \bar{\beta}_b)) \quad (258)$$

$$K_{CI3}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\lambda}_{bk}, \bar{\beta}_a, \bar{\beta}_b) = f^2(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\beta}_a) f(\bar{\lambda}_{bk}, \bar{\lambda}_{bk}, \bar{\beta}_b) \quad (259)$$

$$K_{CI4}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\lambda}_{bk}, \bar{\beta}_a, \bar{\beta}_b) = f(\bar{\lambda}_{ai}, \bar{\lambda}_{ai}, \bar{\beta}_a) f(\bar{\lambda}_{bk}, \bar{\lambda}_{bk}, \bar{\beta}_b) (f(\bar{\lambda}_{aj}, \bar{\lambda}_{aj}, \bar{\beta}_a) - f^2(\bar{\lambda}_{aj}, \bar{1}, \bar{\beta}_a)) - \\ K_{CI1}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\lambda}_{bk}, \bar{\beta}_a, \bar{\beta}_b) \quad (260)$$

$$K_{CI5}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\lambda}_{bk}, \bar{\beta}_a, \bar{\beta}_b) = f(\bar{\lambda}_{ai}, \bar{\lambda}_{ai}, \bar{\beta}_a) f(\bar{\lambda}_{aj}, \bar{\lambda}_{aj}, \bar{\beta}_a) (f(\bar{\lambda}_{bk}, \bar{\lambda}_{bk}, \bar{\beta}_b) - f^2(\bar{\lambda}_{bk}, \bar{1}, \bar{\beta}_b)) - \\ K_{CI2}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\lambda}_{bk}, \bar{\beta}_a, \bar{\beta}_b) \quad (261)$$

$$K_{CI6}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\lambda}_{bk}, \bar{\beta}_a, \bar{\beta}_b) = f(\bar{\lambda}_{ai}, \bar{\lambda}_{ai}, \bar{\beta}_a) f(\bar{\lambda}_{aj}, \bar{\lambda}_{aj}, \bar{\beta}_a) f(\bar{\lambda}_{bk}, \bar{\lambda}_{bk}, \bar{\beta}_b) - \\ K_{CI3}(\bar{\lambda}_{ai}, \bar{\lambda}_{aj}, \bar{\lambda}_{bk}, \bar{\beta}_a, \bar{\beta}_b) \quad (262)$$

For example, if we take

$$\mathbf{\Lambda}_r = \begin{bmatrix} 1 & \frac{\beta_{r1}|h_{r,1}|^2 P_r}{\beta_{r1}|h_{r,1}|^2 P_r + 1} \\ 0 & 1 \end{bmatrix} \quad (263)$$

and assume the degraded channel $X_r \rightarrow Y_1 \rightarrow Y_2$ in the second phase of the FMABC-N protocol, then we can achieve the following rate regions in the second phase:

$$R_{0,1} < \Delta_2 I(U_1^{(2)}; Y_1^{(2)}) - \Delta_2 I(U_1^{(2)}; U_2^{(2)}) = \Delta_2 C(\beta_{r1}|h_{r,1}|^2 P_r) \quad (264)$$

$$R_{0,2} < \Delta_2 I(U_2^{(2)}; Y_2^{(2)}) = \Delta_2 C\left(\frac{\beta_{r2}|h_{r,2}|^2 P_r}{\beta_{r1}|h_{r,2}|^2 P_r + 1}\right) \quad (265)$$

This is the well-known capacity region for the degraded channel $X_r \rightarrow Y_1 \rightarrow Y_2$. However, this may not be optimum due to the opposite data rates $R_{1,0}$ and $R_{2,0}$. Thus, generally it is necessary to optimize Λ_r and $\bar{\beta}_r$ to maximize the entire achievable region.
